Importance of Planting Date for Crops Grown in the Klamath Basin

By Rob Wilson

The uncertainty of irrigation water deliveries from year to year make planting decisions difficult especially when water availability and government programs are unknown before April. This uncertainty is troublesome, but growers should strive to hit the correct planting time if possible. Planting crops at the correct time is one of the most critical farming activities for maximizing yield

potential, avoiding pests, and having timely harvests. Our region has a very limited growing season of frost-free days and many crops require certain weather conditions to maximize yield potential. Below are recommended planting dates for common crops grown in the Klamath Basin.

Winter grains are best planted in October and early November. Forage plantings can be planted earlier in the fall, but early fall planted wheat and barley are often susceptible to spring frost damage as they head out too early the following year.

Spring grains are best planted from late March through April. May and June plantings have lower yield potential and more weed and insect problems due to hot summer temperatures.

Seedling alfalfa can be planted from mid-May through June or in

late August. Late August plantings are preferred in drought years as they require less irrigation water for establishment compared to spring planting. Planting alfalfa after mid-September often results in crop failure due to frost injury to seedling plants.

Onions should be planted in mid-April to early May. Onions planted in late May or early June can reach maturity, but yields are often significantly lower than earlier plantings.

Potato planting date depends on the variety with Mid-May to early June being the most common planting window.

Sudangrass and warm season grass should be planted in early June to avoid spring frosts but still allow time for growth during the hottest months of the year.

Replenishing Soil Moisture Reserves in Established Alfalfa

By Rob Wilson

Many alfalfa fields were deficit irrigated or went without irrigation last year. I'm keeping my fingers crossed for copious amounts of precipitation during March, but winter precipitation up until now is not enough to refill the soil profile in most deficit alfalfa fields. So, what can alfalfa growers do if it remains dry? In a perfect world, growers would have plenty of irrigation water to irrigate all fields, but 2022

will likely come with irrigation water restrictions. As such, I advise alfalfa growers to check soil moisture in their fields and try to accurately refill the soil profile in dry fields and conserve water in fields that do not need deep irrigation.

How do you determine how much irrigation water is needed

Alfalfa roots often extend beyond 5ft in the soil; it takes a large amount of water to refill the soil profile.

to refill the soil profile in deficit irrigated alfalfa? The first step is to check soil moisture by digging in the soil. Since alfalfa has a 3-to-6-foot root system this means you need to dig at least 3 feet deep. I find a spiral soil auger works well for checking soil moisture in alfalfa. You can auger 6 inches of soil at a time and check soil moisture as you go down to 3 or 4 feet. Currently, the top 8 inches of soil are wet at IREC, but the remaining 1 to 4 ft are very dry. This means spring irrigation needs to re-wet a 3 ft root zone to refill the soil profile. The amount of irrigation water needed to refill the root zone depends on your soil type. In this example, a sandy loam soil would require 4.5 inches of irrigation water or a 14hour wheel-line set. In a clay loam soil, 7.0 inches of irrigation water or a 22-hour wheel-line set is needed to refill the soil profile as clay soils hold more water than sandy soils.

Alfalfa Irrigation Strategies for Maximizing Yield with Limited Water It is important to determine what fields will be irrigated fully, what fields will receive partial irrigation, and what fields will not be irrigated. I recommend prioritizing your most productive fields for full irrigation. In fields that can only receive partial irrigation, apply allocated water to refill the soil profile before 1st cutting and remaining water before 2nd cutting. The first two cuttings often make up 70% of total yield in a 3-cut system, and once alfalfa is drought stressed it will go dormant until fall. It makes little sense to deficit irrigate all fields throughout the season especially after fields stop growing due to drought stress. It is also wise to not irrigate alfalfa with poor stands and low yield potential and instead allocate more water to healthy productive fields.

Latest Alfalfa Variety Yield Results

University of **California** Agriculture and Natural Resources

Research and Extension Center System

By Chris DeBen, Dan Putnam, UC Davis

Choosing superior varieties of alfalfa is a significant economic factor for alfalfa growers. Many commercial varieties are currently available, enabling wide range of options. UC trials provide unbiased data from a wide range of environments related to variety performance of alfalfa. In California, alfalfa is grown from the Oregon border to the Mexican border, and throughout the Great Central Valley, which consists of the Sacramento and San Joaquin Valleys. The tables below represent sites using a 3-4 cut system (dormant varieties) in the Intermountain Region. See the University of California Alfalfa and Forages Website for full report and more information. http://alfalfa.ucdavis.edu

Yield Studies: The California Alfalfa Cultivar Yield, Fall Dormancy, and Forage Quality Trials are open to any certified alfalfa cultivar, which is sold or is likely to be sold in California. Blends or brands (unless they are certified blends) are not included in these trials. Experimental cultivars with a high

likelihood of release within the next few years are tested as space permits.

Cutting schedules were determined by the most common practice in that region and are the same for all varieties within a trial. The data is obtained from each of the locations and analyzed and summarized at the UC Davis campus.

2017 Planted Tulelake Yield Trial: This trial was planted with 44 entries on May 22, 2017. **IN 2021, THIS TRIAL RECEIVED ZERO ADDITIONAL IRRIGATION WATER** due to the sudden cutoff of water in the Klamath irrigation project. The site received approximately 6" of rainfall over the winter. Thus, 2021 was basically a dryland trial with the only water coming from residual soil moisture. Two cuttings were taken during the 2021 season with the first cutting taking place on June 17, 2021. Surprisingly, the first two cuttings of 2021 were higher yielding than the first two cuttings under fully irrigated conditions in 2020 (see results on-line at https://alfalfa.ucdavis.edu for previous year's trials). The trial demonstrated that substantial yields can be achieved with natural rainfall if residual soil moisture is available in soils with high water holding capacity. Single year results for 2021 harvests are provided in a separate table. The average yield across all varieties in 2021 was 6.6 tons/acre.

2017-2021 YIELDS. TULELAKE ALFALFA CULTIVAR TRIAL. TRIAL PLANTED 5/22/17

Trial seeded at 25 lb/acre viable seed at Intermountain Research and Extension Center, Tulelake, CA.

Entries follow ed by the same letter are not significantly different at the 10% probability level according to Fisher's (protected) LSD.

FD = Fall Dormancy reported by seed companies.

*No supplemental irrigation used for 2021 harvests (only natural rainfall and residual soil moisture)

Note: Single year data sh	ould not	be used to evalu	ate alfalfa variet	ies or choose a	alfalfa cultivars

2021 YIELDS, TULELAKE ALFALFA CULTIVAR TRIAL (DROUGHT). TRIAL PLANTED 5/22/17 Note: Single year data should not be used to evaluate alfalfa varieties or choose alfalfa cultivars

Trial seeded at 25 lb/acre viable seed at Intermountain Research and Extension Center, Tulelake, CA.

Entries follow ed by the same letter are not significantly different at the 10% probability level according to Fisher's (protected) LSD.

FD = Fall Dormancy reported by seed companies.

*No supplemental irrigation used for 2021 harvests (only natural rainfall and residual soil moisture)

Cutting Strategies for Maximizing Revenue and Alfalfa Health during Drought

By Rob Wilson

The decision on when alfalfa is cut through the season has a large impact on alfalfa yield, alfalfa quality, and farm revenue. It boils down to the classic yield versus forage quality trade-off Dan Putnam has preached about for years. Longer cutting intervals equal higher yield but lower quality. Shorter cutting intervals equal lower

yield but higher quality. In Tulelake, 4 cuttings per year is common. In other part of Siskiyou County, 3 cuttings per year is common. Four cuttings per year favor quality with most cuttings testing supreme or premium. Three cuttings favor yield with least one cutting testing below premium. Both cutting strategies have merit, and some growers utilize both strategies in different fields.

All cutting schedules should strive to maximize 1st cutting yield for the desired quality! A mistake I see many producers make is taking first cutting too early. The first of

June rolls in and everyone breaks out the swather and cuts away. In some years the alfalfa is ready to harvest the first week of June but in others the alfalfa is quite short (supreme+ quality). Harvesting 1st cutting too early can result in a yield penalty of 0.5 to 0.75 tons/acre without a significant bump in hay price especially in high price years. 1st cutting is the biggest cutting of the year and can make up 35% to 50% of total yield.

Space cutting schedules across the growing season to avoid ending up with 3.5 cuttings per year! Growers should avoid 4-cut schedules that result in 4th cutting regrowth that is too short to harvest but too tall to leave standing going into winter. In this situation, growers do not capture the yield increase from a 3-cut system, and they often do not achieve test hay in every cutting like a 4-cut system. A good planning exercise is at the time of 1st cutting calculate the number of days left until the last date you feel comfortable taking 4th cutting and then divide by 3. For example, if you select September 7th as your last harvest date, cutting 1st cutting on June 1 would equal 33 days between cuttings, cutting on June 8th would equal 30 days between cuttings, and cutting on June 15th would equal 28 days between cuttings.

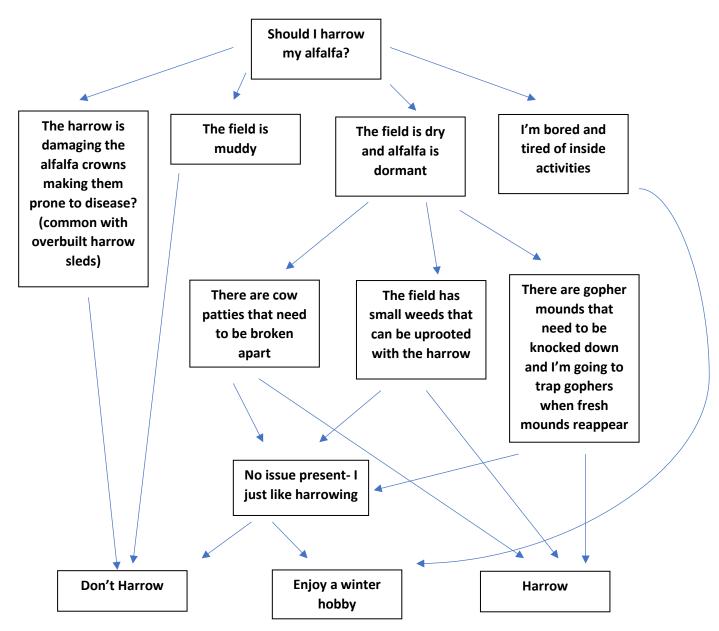

Consider drought and limited water in your cutting schedule. Sometimes it's ok to delay first cutting and apply another irrigation before 1st cutting if your alfalfa needs water and irrigation deliveries are not available soon. Last year, everyone wanted water at the same time after 1st cutting creating a major problem on timely irrigation deliveries. It makes no sense to take first cutting early only to wait two weeks for your next irrigation water delivery.

Longer intervals between cutting (32+ days) or a 3-cut system has several advantages during drought especially in fields that lack irrigation water. In this scenario, growers can maximize first cutting yield by delaying harvest until premium or good quality, go for high yield at 2nd cutting, and then allow alfalfa to go dormant or get a 3rd cutting depending on soil moisture. Longer cutting intervals equal higher alfalfa yields and better health as alfalfa has a chance to rebuild carbohydrate root reserves needed for winter survival and regrowth. Cutting alfalfa frequently in a 4-cut system stresses alfalfa and can negatively affect next year's growth especially when alfalfa is stressed. Several studies conducted by Steve Orloff showed that alfalfa yields and stand longevity diminished over time with a 4-cut system versus a 3-cut system.

Too Harrow or Not to Harrow Alfalfa?

By Rob Wilson

A common start to the field season for alfalfa growers is to break out the tractor and harrow all alfalfa fields. Many people find a sense of satisfaction and optimism when a field is freshly harrowed, but is harrowing all alfalfa fields a good decision? My opinion is no. Harrowing has advantages and disadvantages, but I advise growers to ask yourself why am harrowing and is it worth the time and diesel fuel. Below is a decision chart to consider before harrowing alfalfa this winter.

2021 Small Grain Variety Trial Report

University of California Agriculture and Natural Resources

Research and Extension Center System

Rob Wilson, Center Director/Farm Advisor; Darrin Culp, IREC Superintendent of Agriculture and Kevin Nicholson, IREC Staff Research Associate II. University of California Intermountain Research & Extension Center, 2816 Havlina Rd. Tulelake, CA. 96134 Phone: 530/667-5117 Fax: 530/667-5265 Email: rgwilson@ucdavis.edu

Introduction This report summarizes grain yield and agronomic characteristics for public and private entries in IREC's 2021 small grain variety testing. 2021 IREC grain trials were irrigated using well water thanks to a well on site and TID support. This project is a cooperative effort with Oregon State University's Cereal Variety Testing organized by Ryan Graebner and University of California Small Grain Breeding Programs. Research received funding support from the California Wheat Commission, private seed companies, and UC ANR. Trials conducted during the 2020-2021 growing season

included: winter wheat, winter barley, spring hard wheat, spring soft wheat, and spring barley. Entries included released and experimental varieties adapted to Tulelake's high desert climate.

Grain yield and agronomic data was collected by IREC staff. Grain protein and test weights were generated in collaboration with Ryan Graebner, Oregon State University. Small grain yield and quality for other locations around the Northwest can be found at <u>https://cropandsoil.oregonstate.edu/wheat/osu-wheat-variety-trials</u>. UC small grain variety trial summaries for multi-year and multi-trial data can be found at <u>http://smallgrainselection.plantsciences.ucdavis.edu/.</u>

2021 General Trial Information for all trials

Location:	Intermountain Research and Extension Center, Tulelake, CA
Soil Type:	Tulebasin mucky silty clay loam
Weed Control:	Rhomene MCPA @ 1 pt. /Acre; Detonate @ 2 fl oz./Acre
Plot size:	Winter Trials 100 ft ²
	Spring Trials 66.5 ft ²
Seeding Rate:	100 lbs./Acre
Row Spacing:	6 Inches
Number of Reps:	4

Hard Winter Wheat Trial

Planting Date:	10/15/2020
Previous Crop:	Sudan Grass
Spring 2021 Soil Test N:	14.2 ppm (51 lbs. N/Acre)
Fertilizer:	Season total Nitrogen was 192 lbs. N/Acre applied through the season. 22 lbs.
	N/A at planting (10/14/2020), 90 lbs. N/A early through late tillering
	(4/19/2021), 80lbs. N/A through stem elongation (5/21/2021), 30 lbs. N/A at
	flowering (6/10/2021).
Irrigation Quantity:	Solid-set sprinklers 18.87 Acre inches (final irrigation 6/30/2021)
Harvest Date:	8/18/2021

Variety Highlights: Several varieties performed well in 2021. WB4394 was the highest yielding, however it was prone to lodging. Millie, LWH18-0122 and OR2170052H had similar yields but less lodging compared to WB4394. Three varieties met the quality protein standard of 13%, LCS Evina, LCS Jet and LWH18-0122. All were hard red type. Breck, Snowmass 2.0 and PN13201002-04 plots were almost 100 percent lodged.

Soft White Winter Wheat Trial

Planting Date:	10/15/2020
Previous Crop:	Sudan Grass
Spring Soil Test N:	14.2 ppm (51 lbs. N/Acre)
Fertilizer:	Season Total Nitrogen was 142 lbs. N/Acre applied through the season. 22 lbs. N/A at
	planting (10/14/2020), 90 lbs. N/A early through late tillering (4/19/2021), 80lbs. N/A
	through stem elongation (5/21/2021)
Irrigation Quantity:	Solid-set sprinklers 18.87 Acre inches (final irrigation 6/30/2021)
Harvest Date:	8/18/2021

Variety Highlights: The awnless variety LCS Blackjack continues to perform well and may be suitable as a forage or seed crop. Other varieties in the 2021 trial with high yields over the three-year period from 2018-2020 include Bobtail (awnletted), LCS Hulk and WB1783. Several varieties were very prone to lodging in the trial. Varieties with high yield and low lodging were LWW-18-5080, LCS Artdeco, LCS Blackjack and SY Assure.

Winter Barley Trial

Planting Date:	10/15/2020
Previous Crop:	Sudan Grass
Spring Soil Test N:	14.2 ppm (51lbs. N/Acre)
Fertilizer:	Season total Nitrogen was 67 lbs. N/Acre applied through growing season. 22 lbs. N/A
	at planting (10/14/2020), 15 lbs. N/A at tillering (4/9/2021) and 30 lbs. N/A during stem
	elongation through jointing (5/21/2021).
Irrigation Quantity:	Solid-set
	sprinklers 14.67
	Acre inches (final
	irrigation
	6/4/2021)
Harvest Date:	8/2/2021
Variety Highlights: Al	

Variety Highlights: All malt varieties achieved protein below the standard 11% in 2021. Thunder and Wintmalt had low protein and high yield. Thunder is a recent release from the Oregon State University Barley Breeding Program. Alba, a feed barley, was the only variety to show significant lodging.

2021 IREC Irrigated Winter Barley Agronomic Characteristics.

						Plant	%		
			Grain Yield	Heading	Maturity	Height	Lodged	Bushel	Protein

Spring Soft Wheat Trial

Planting Date:	4/15/2021
Previous Crop:	Sudan grass
Spring Soil Test N:	13.9 ppm (50 lbs. N/Acre)
Fertilizer:	Season total nitrogen was 182 lbs. per acre
	applied through the season. 22 lbs. N/A at
	planting (4/14/2021), 30 lbs. N/A at tillering
	(5/21/2021), 130 lbs. N/A through early boot
	(6/10/2021).
Irrigation Quantity:	Solid-set sprinklers 22.11 Acre inches (final
	irrigation 6/30/2021)
Harvest Date:	8/17/21

0/

Variety Highlights: Lodging was a significant issue for the spring wheat trial in 2021. WB6121 and UI Cookie were the only varieties with 30% or less lodging. Yields may have been lower in 2021 compared to 2020 because of the high amount of lodging. WB6341,

Tekoa and UI Cookie (all high yields in 2021) were the highest yielding released spring soft wheat varieties over a three-year period from 2018-2020.

Harvest Date:	8/17/2021	

Variety Highlights: All varieties in the 2021 Spring Hard Wheat Trial met the protein standard of 13% with the nitrogen fertilizer application applied during flowering. WB9668 and WB7202 CLP had protein over 15% in addition to high yield. UC-Central Red, WB9662 and Patwin 515 had 0% lodging in a year prone to lodging.

2021 Potato Variety

Development

University of California Agriculture and Natural Resources

Research and Extension Center System

Rob Wilson, Center Director/Farm Advisor; Darrin Culp, IREC Superintendent of Agriculture and Kevin Nicholson, IREC Staff Research Associate II. University of California Intermountain Research & Extension Center, 2816 Havlina Rd. Tulelake, CA. 96134 Phone: 530/667-5117 Fax: 530/667-5265 Email: <u>rgwilson@ucdavis.edu</u>

Three potato variety trials were conducted at the Intermountain Research and Extension Center in Tulelake, CA. Trials were categorized by market type and included a Russet trial with 17 entries, a Specialty trial with 10 entries, and a Chipping trial with 12 entries. Entries included selections from the Western Regional (WR) variety development program, Southwest Regional (SWR) variety development program, and varieties of local interest. The tables below highlight some of the results from these trials.

Influence of Potato Vine Kill Timing and Skin-set duration on Black Dot (*Colletotrichum coccodes*) and Potato Quality

Rob Wilson, Center Director/Farm Advisor; Darrin Culp, Superintendent of Agriculture; Kevin Nicholson Staff Research Associate. University of California Intermountain Research & Extension Center; 2816 Havlina Rd. Tulelake, CA. 96134 Phone: 530/667-2719 Fax: 530/667-5265 Email: <u>rqwilson@ucdavis.edu</u>

Introduction

Black dot fungal structures (sclerotia) on harvested tubers are a consistent problem for fresh market potato producers throughout California. Tubers infected with black dot have a rash like appearance that is especially evident on red and yellow skin potatoes making them unmarketable. Black dot infection on below ground stems and stolons occurs within weeks of sprouting. Fungicides are effective at suppressing the black dot during the growing season, but fungicides have failed to reduce severity of black dot sclerotia on daughter tubers. Cultural management and harvest timing can influence black dot on daughter tubers. Studies suggest the duration between haulm (stem) senescence and harvest increases severity of black dot; high soil moisture increases black dot, and plant stress can increase severity of black dot. These findings served as a guide for setting up the experiment. The primary study objective was to document the effect of vine kill timing and skin set duration on yield and black dot under California conditions.

2021 Site Information

- Soil type- mucky silty clay loam-6% OM
- Planting Date- May 18, 2021
- Irrigation solid-set sprinklers
- Potato Spacing- 36-inch rows with 10 inch seed spacing
- **Design-** Split Block with 4 blocks (reps)

2021 Study Methods

The study was conducted in field at the Intermountain REC with a long history of natural black dot infection. The study was set up in a split-plot design with four replications. Dark Red Norland, an early maturing red skinned variety was grown under normal conventional management conditions. Vines were killed at three timings: 95% green on 8/5/21 (77 days after planting DAP), 50% green on 8/18/21 (92 DAP), and 10% green on 9/1/21 (106 DAP) (figure 1).

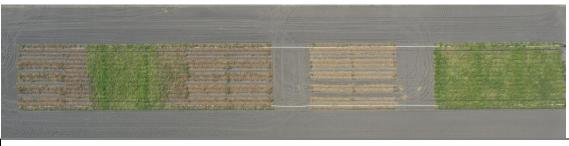

Figure 1. Drone photo of different vine kill timing plots shortly after the 50% vine kill timing.

Vines were killed using Reglone and rolling and soil moisture was kept around 60% ASM from vine kill to harvest to minimize bruising. For each vine kill timing, potatoes were harvested 2 weeks after vine kill or 4 weeks after vine kill. Data included tuber yield, tuber size, tuber skinning, tuber bruise, and the incidence and severity of black dot on daughter tubers. Tuber yield and size was determined by running all potatoes from each plot across an automated grade-line. Black dot incidence and severity was determined by evaluating percent coverage of black dot infection on a 20 tuber sub-sample from each plot. Skinning severity was evaluated by placing 20 tubers from each plot in a cement mixer without paddles for 1 minute at harvest (figure 2.)

Figure 2. Cement mixer

setup for evaluating tuber

Results

2021 weather was unusually hot and dry in spring and early summer (CA CIMIS Station # 91). Potato yields differed significantly between treatments with the last vine kill timing having the highest yield in most categories (Table 1). The early 95% green vine kill timing had

treatments with the last vine kill timing having the highest yield in most categories (Table 1). The early 95% green vine kill timing had the lowest yield, tubers per plant, and tuber size. The 50% green vine kill timing had lower total yield compared to the 10% vine kill timing, but average tuber size, tubers per plant, and 4-to-10-ounce tuber

compared to the 10% vine kill timing, but average tuber size, tubers per plant, and 4-to-10-ounce tuber yield were similar between timings. Not surprisingly there were few yield differences between 2-week and 4-week skin set periods for each vine kill timing (Table 1).

Vine kill timing and skin set duration had a significant affect on black dot coverage with the 95% vine kill timing having the least amount of black dot (Table 2). The 50% green vine kill timing harvested 2-week after vine kill had less black dot compared to the 10% vine kill timing. On the flip side, the 95% green and 50% green vine kill timings harvested 2 weeks after vine kill had more tuber skinning compared to other treatments (Table 2). Tuber shape uniformity and tuber quality were similar across treatments except for the 95% green treatment having slightly less growth cracks compared to the 10% green vine kill timing (Table 2).

In summary, harvesting Dark Red Norland early in the season while vines were still green and shorting the skin set duration reduced the severity of black dot tuber blemish. As a trade-off, the 95% green vine kill timing had lower yield and smaller tubers. Tuber skinning increased for the 95% green vine kill timing if the skin set duration was 2 weeks compared to 4 weeks. These results agree with previous published research, and they serve as a guide for growers trying to weigh the trade-off of maximizing yield versus minimizing black dot tuber blemish as the reduction in black dot from early vine kill may outweigh the reduction in yield.

2021 Fungicide Screening for In-Season Strategies for Suppressing White Rot in Onions

Rob Wilson, Center Director/Farm Advisor; Darrin Culp, Superintendent of Agriculture; Kevin Nicholson Staff Research Associate. University of California Intermountain Research & Extension Center; Jeremiah Dung, Plant Pathologist, Oregon State University Central Oregon Agricultural Research Center; 2816 Havlina Rd. Tulelake, CA. 96134 Phone: 530/667-2719 Fax: 530/667-5265 Email: rgwilson@ucdavis.edu

Introduction

Management of white rot disease in onions and garlic is focused on prevention, containment, reduction of inoculum before planting, and suppression with fungicides. Application of penthiopyrad (Fontelis) and/or tebuconazole (Tebustar) in-furrow at planting is the standard fungicide treatment for suppressing white rot in California. Numerous studies have shown these fungicides applied in a concentrated band at planting significantly reduce white rot severity in onions and garlic. Fungicide application in-furrow can prevent economic loss in years with low disease severity or in fields with low inoculum. Unfortunately, fungicides fall short of preventing economic loss in years when weather favors disease development or in fields with high inoculum levels. The reason fungicides fail to suppress white rot is thought to be related to decreasing fungicide concentration over time. Fungicide residue in-furrow decreases in the soil throughout the growing season for a variety of reasons including absorption to the soil, degradation by soil microbes, and leaching.

The objective of this study was to investigate methods for increasing fungicide levels in the soil during summer and early fall. The project investigated in-season banded fungicide application and the use of soil surfactants/penetrants with fungicides. In season banded applications were directed at the base of plants in each seed row at the time of cultivation 2 months after planting.

2021 Site Information

- Soil type- mucky silty clay loam-6.5% OM
- Growing season- May 6, 2021 to October 5, 2021
- Irrigation solid-set sprinklers
- **Onions-** 36 inch beds with 4 seed-lines spaced 6 inches apart; 2-inch seed spacing; Senscient processing variety
- Design- RCB with 5 blocks (reps)

2021 Study Methods

In early May 2021, the field was rototilled and beds were shaped before onion planting. Fungicide treatments were applied in-furrow at planting time. In-furrow fungicides were applied using Teejet 8001 EVS nozzles @ 30 psi. The nozzles were mounted on the onion planter to apply a 3-inch band directly over the seed-line after seed placement but before furrow closure. In-season fungicide application occurred when onions were in the 5-6 leaf stage on 6-30-2021. Fungicides were applied with CO2 powered backpack sprayer using 80015 EVS drop nozzles placed 1 ft above the onion leaves at 50 GPA. Onion stand density was measured in each plot by counting the number of green onions in all seed lines for the entire plot length. Onion vigor (color, height, and leaf cover) was visually estimated in each plot using a 0 to 10 scale, with 10 = highest vigor. Late season visual leaf dieback ratings were taken starting 8-30-2021. The number of plants with leaf dieback per plot and a visual estimate of the percentage of total leaves with leaf dieback per plot was recorded. Onion yield was measured by harvesting all onions in each plot on 10-5-2021. Onions were run across a grade-line to remove loose soil and green tops. Onion bulbs were hand-sorted based on the presence of white-rot. A total weight was recorded for disease-free onions and onions with white-rot symptoms (decay through 1st scale, mycelium, or sclerotia).

Results

Spring and early summer weather was unusually hot and dry in 2021 (data not shown) which likely hampered early season white rot development. Fungicide treatments did not have an influence on spring onion stand or early season vigor (Table). This result suggests the fungicide treatments were safe on onions. The first sign of white rot mycelium growth and leaf dieback was in the last week of August. Leaf dieback in August and September was highest in the untreated control (Table). All fungicides had lower leaf dieback compared to the untreated control, but leaf dieback did not differ

Figure. Drone photo of plot area late season at the start of onion lodging.

between fungicide treatments. This same trend occurred at harvest with all fungicide treatments having high disease-free yield and lower diseased yield compared to the untreated control. Total onion yield was similar across all treatments. Treatments with Tebustar applied in-furrow and Fontelis banded at the time of cultivation had the lowest diseased yield numerically, but this treatment trend was not statistically significant. All treatments including the untreated control had relatively low disease loss which was surprising as the field site had high sclerotia counts before planting. Additional evaluation of in-season fungicides in a year with high disease severity is recommended as disease pressure was relatively low in 2021.

Plant Growth Regulator Testing to Prevent Spring Barley Lodging in Tulelake

Rob Wilson, Center Director/Farm Advisor; Darrin Culp, IREC Superintendent of Agriculture. University of California Intermountain Research & Extension Center, 2816 Havlina Rd. Tulelake, CA. 96134 Phone: 530/667-5117 Fax: 530/667-5265 Email: rgwilson@ucdavis.edu

Introduction: Tulelake's climate and soils are favorable for irrigated barley production, and growers consistently obtain some of the highest barley yields reported in California. The downside to these high yields is several barley varieties tend to lodge, the bending over of the stems near the ground level, in Tulelake. One solution to lodging is to apply a plant growth regulator (PGR) that shortens the internodes and strengthens the stem through inhibition of cell elongation. This study tested the effectiveness of PGRs applied at different timings and rates for reducing spring barley lodging. A similar study was conducted in 2018 and 2019 with winter wheat and 2020 with spring barley; report summaries are cited in IREC Research Reports #187, #192, and #196.

Methods: The 2021 study was established in April using the spring 2-row malt barley variety 'Copeland'. The broadcast study was set up as a RCB design with four replications using 9 ft by 21 ft plots. Treatments included an Eastman PGR (Test PGR) with the active ingredient, chlormequat chloride, and a Syngenta PGR (Palisade) with the active ingredient, trinexapac-ethyl, broadcast applied at 20 gallons per acre alone and/or in combination with the fungicide Quilt Xcel for suppression of stripe rust. PGR treatments were applied at three application times: tillering (23), early stem elongation (31-32), and flag leaf emergence (38). The trial included a standard nitrogen fertilizer control (70# N/A) and high nitrogen fertilizer control (110# N/A). Data collected includes crop injury, stem thickness, plant height, stripe rust incidence, lodging, grain yield, and grain quality.

Results: PGR treatments did not cause phytotoxicity after all application times (data not shown). PGR treatments influence on plant height and lodging was variable in 2021, unlike 2020 where PGR's applied at stem elongation or split applied at stem elongation and flag leaf emergence reduced plant height at anthesis compared to the high fertility control (Table 1). Barley stem thickness, seedhead production, and the incidence of stripe rust were similar across treatments (Table 1). PGR treatments increased barley grain yield compared to the controls even though plant height and lodging were variable (Table 2). Barley bushel weight and kernels per 10 seedheads were similar across treatments. PGR treatments where the test PGR was applied at tillering had lower seed weight (g) per 1000 barley seeds compared to PGR treatments with later application dates and the controls.

Brewers Association Nitrogen Trial (BANT)

Margaret Halstead, Daniela Carrijo, Scott Fisk, Pat Hayes, and Campbell Morrissy (Oregon State University, Corvallis, OR)

Darrin Culp, and Rob Wilson (UC Davis IREC, Tulelake, CA)

The Brewers Association Nitrogen Trial (BANT) was comprised of fallplanted malting barley lines (two named varieties, and three experimental lines) grown at three locations per year (Corvallis, and Pendleton, OR; Tulelake, CA; and Aberdeen ID) to characterize: Agronomic performance; Response to nitrogen fertilization at flowering; And malting and beer quality and the effects of environment ("terroir") on beer flavor. The experiment was grown for two years (2020 and 2021 harvest). The focus of this report is on data from Tulelake for three of the BANT barleys: Thunder, Lightning, and DH142010, a potential variety of interest to Admiral Malting (CA). We present agronomic data from 2020 and 2021 and beer data from 2020. A detailed report on the full experiment is in preparation and will soon be submitted for publication.

General information for both years

Location: Intermountain Research and Extension Center, Tulelake, CA Soil type: Tulebasin mucky silty clay loam Weed control: Rhomene MCPA @ 1 pint/Acre and Detonate @ 2 fl. oz/Acre Plot size: 100 ft² Seeding rate: 86 lbs/Acre Row spacing: 6 inches Number of reps: 4

Trial information

Table 1. Management details for Brewers Association Nitrogen Trial (BANT) barley grown at the Intermountain Research and Extension Center (IREC) in the 2020 and 2021 harvest seasons.

	2020 harvest	2021 harvest
Planting date	10/22/2019	10/15/2020
Previous crop	Sudangrass	Sudangrass
Fertilizer at planting	22 lb/ac N (11-52-0)	22 lb/ac N as (11-52-0)
Spring soil test N	9.5 ppm N	15.7 ppm N
Fertilizer treatments	 40 lb/ac N for all plots (green-up) Additional 20 lb/ac N as urea for high-nitrogen treatment (early heading) 	 15 lb/ac N for all plots (green-up) Additional 20 lb/ac N as urea for high-nitrogen treatment (early heading)
Irrigation	13.02 acre inches	14.67 acre inches
Average heading date	05/28/2020	06/03/2021
Harvest date	07/29/2020	07/29/2021

Variety highlights

Thunder (released by Oregon State University in 2019) had the highest yields and the lowest percent grain protein of the three varieties in both the 2020 and 2021 growing seasons. Thunder is recommended by the American Malting Barley Association (AMBA) and may be available for contracting in the Klamath Basin with Great Western Malting.

Lightning (released by Oregon State University in 2020) has facultative growth habit and excellent disease resistance but is not on the AMBA recommended list. It may be of interest to craft maltsters and brewers; growers are urged to secure a contract before growing the variety. DH142010 is a potential variety of particular interest to Admiral Malting, due having the British variety "Maris Otter" in its pedigree.

Nitrogen fertilization at flowering did increase grain protein, but values were still within AMBA guidelines. The additional fertilization may allow growers to fine-tune production to meet all-malt or adjunct malting specifications.

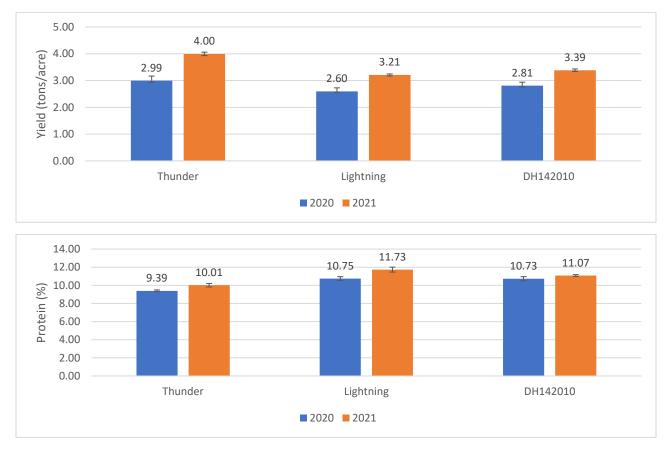

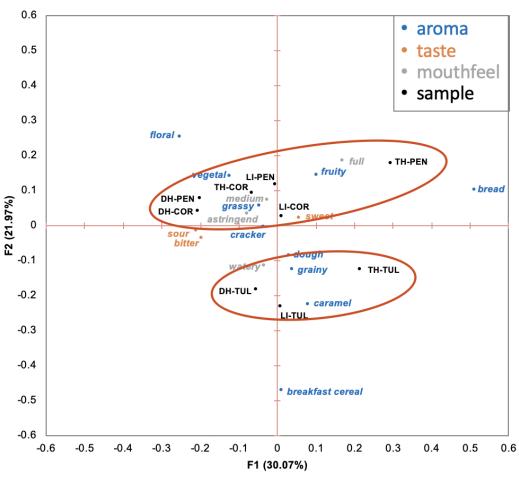

Fig 1. Yield (top) and percent grain protein (bottom) for 2020 and 2021 growing seasons for three selected barley lines from the Brewers Association Nitrogen Trial (BANT).

Malting and brewing highlights

Thunder, Lightning, and DH140963 (a discontinued experimental variety) were malted at the OSU Barley Project malt house and used to brew experimental beers in collaboration with Deschutes Brewing. These beers were compared to beers made from the same barley lines grown at other locations (Corvallis, OR and Pendleton, OR). Figure 2 shows the distinct flavor profile of beer brewed from barley grown at Tulelake in comparison with the other two locations.

F1 + F2 = 52.03%

Fig 2. Sensory evaluation of beers brewed with three different barley lines (Thunder [TH], Lightning [LI], and DH140963 [DH]) at three locations (Corvallis [COR], Pendleton [PEN], and Tulelake [TUL]). The Tulelake grown lines formed a distinct grouping and plotted with dough, grainy, and caramel aromas.

Beer brewed from DH142010 grown at Tulelake in 2021 was evaluated for flavor characteristics in a separate study, which is in review for publication. Despite similarities between the malting quality of DH142010 and the control (Copeland), beer brewed with the DH142010 malt produced unique flavors: it was higher in butter, cracker, grainy, and vegetal flavors and lower in fruity and sweet aromatic than Copeland. DH142010 is under consideration for release and, with sufficient industry interest, could be a promising niche variety for the Klamath Basin. A seed increase of DH142010 is currently underway at IREC.
