

Removing nitrate and phosphate from agricultural runoff or drainage

Collaboration:

- Richard Smith and Mike Cahn
- Tom Bottoms
- Cooperating growers

Funding:

- Leafy Greens Research Board
- CDFA - FREP

Surface water monitoring shows high $\text{NO}_3\text{-N}$ is common...

● = Good ● = Slightly Impacted ● = Impacted ● = Very Impacted ● = Severely Impacted

Irrigation and fertilization practices can be improved ...

... but some wastewater remediation will likely be needed to consistently meet environmental targets

What remediation practices can remove soluble nutrients ?

- Conservation practices that remove sediment are generally ineffective in removing *soluble* nutrients

- Biological denitrification has potential

Biological denitrification :

Requirements for denitrification:

- Anaerobic conditions
- Bacteria capable of reducing $\text{NO}_3\text{-N}$
- Labile (microbially-available) carbon to support the reaction

Denitrification occurs in wetlands, but ...

- **denitrification rate is usually limited by carbon availability, meaning that nitrate removal per unit land area is low**
- **wildlife attraction can raise microbial food safety concerns**

Denitrification bioreactors (DBR) :

**Organic waste material
to provide labile carbon**

Building a DBR Salinas Valley, 2011 :

chipped construction wood from
Monterey Regional Waste
Management District

DBR 1
34 cubic yards
treat tile drain water
May 2011

DBR 2
17 cubic yards
treat tile drain water
June 2011

DBR 3
16 cubic yards
treat surface runoff
June 2012

Continuous pumping into DBRs from tile drain sump or tailwater pond

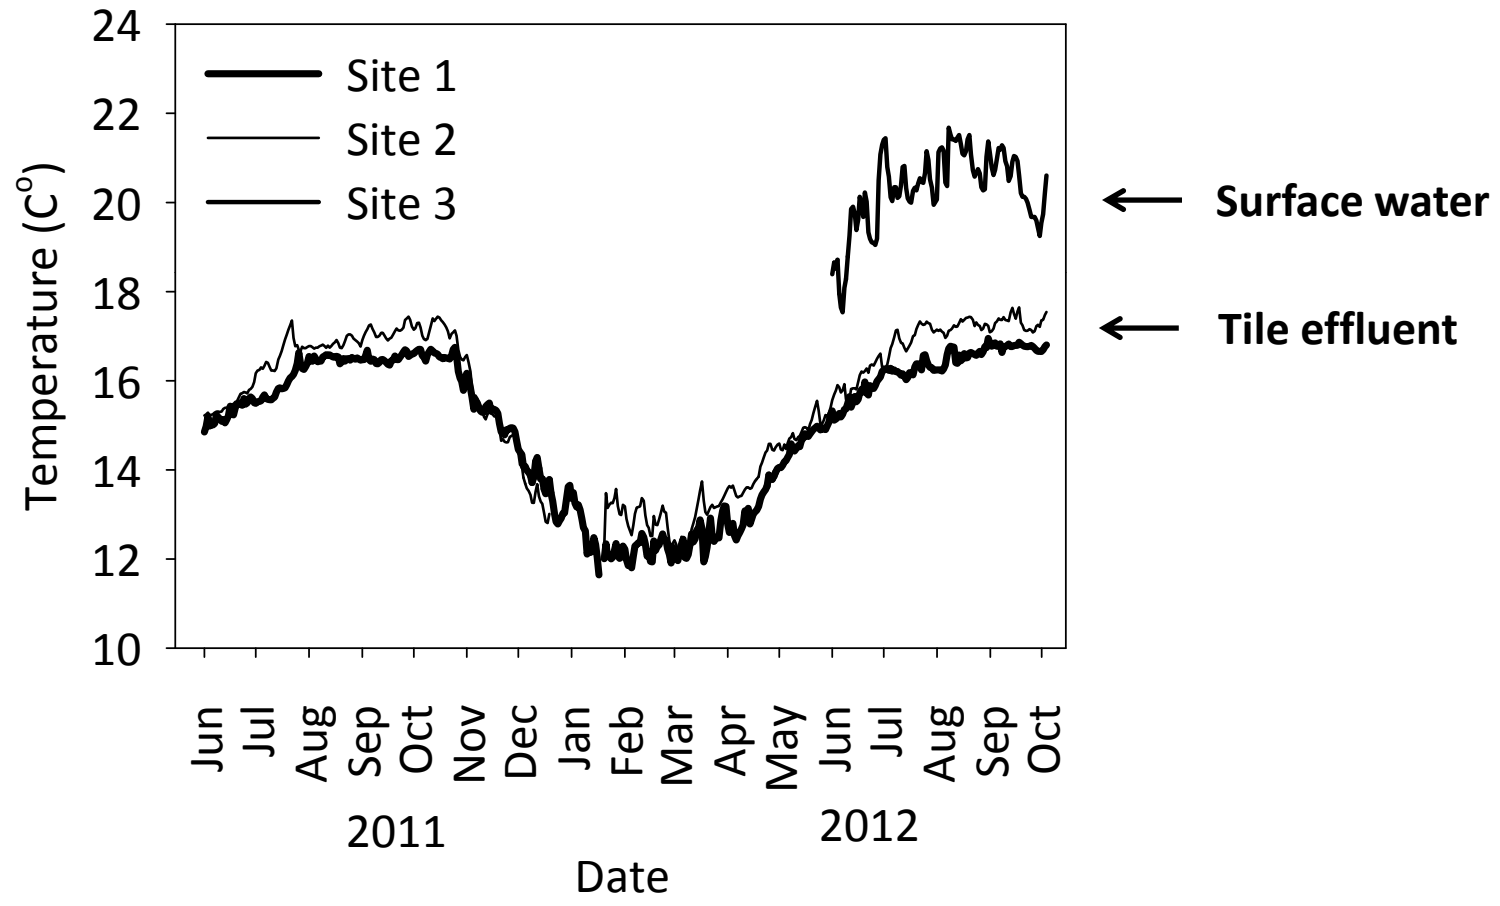

DBR outlet drains into surface ditch after approximately 2 days of residence time

- **Surface water pretreated with polyacrylamide (PAM) to keep sediment out of the bioreactor**

Moderate temperature allows denitrification all year :

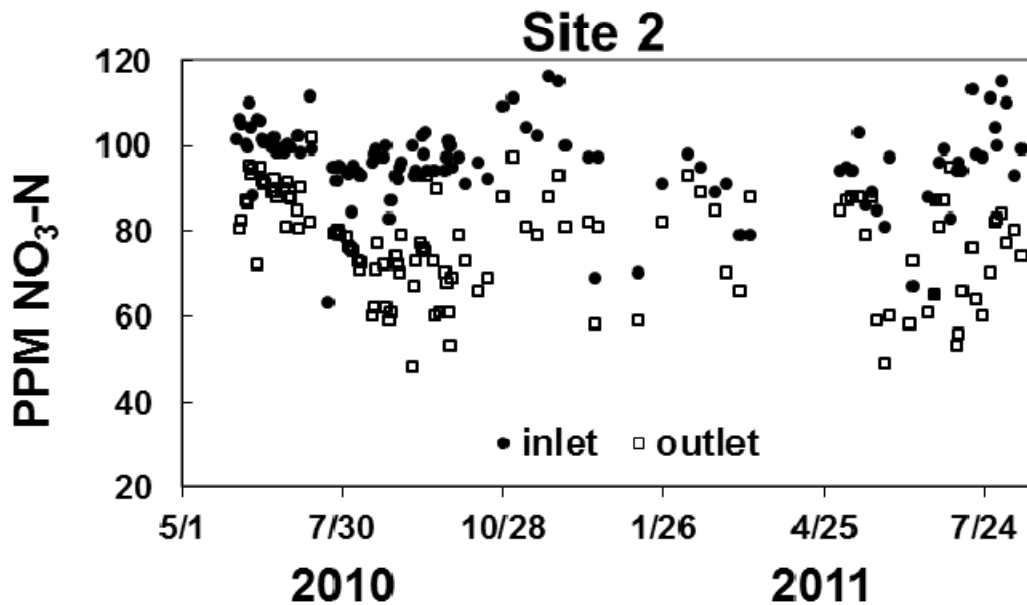

DBR performance on tile drain effluent :

Denitrification rates achieved

**Summer average:
≈ 8 PPM NO₃-N / day**

**Winter average:
≈ 5 PPM NO₃-N / day**

DBR performance on surface runoff :

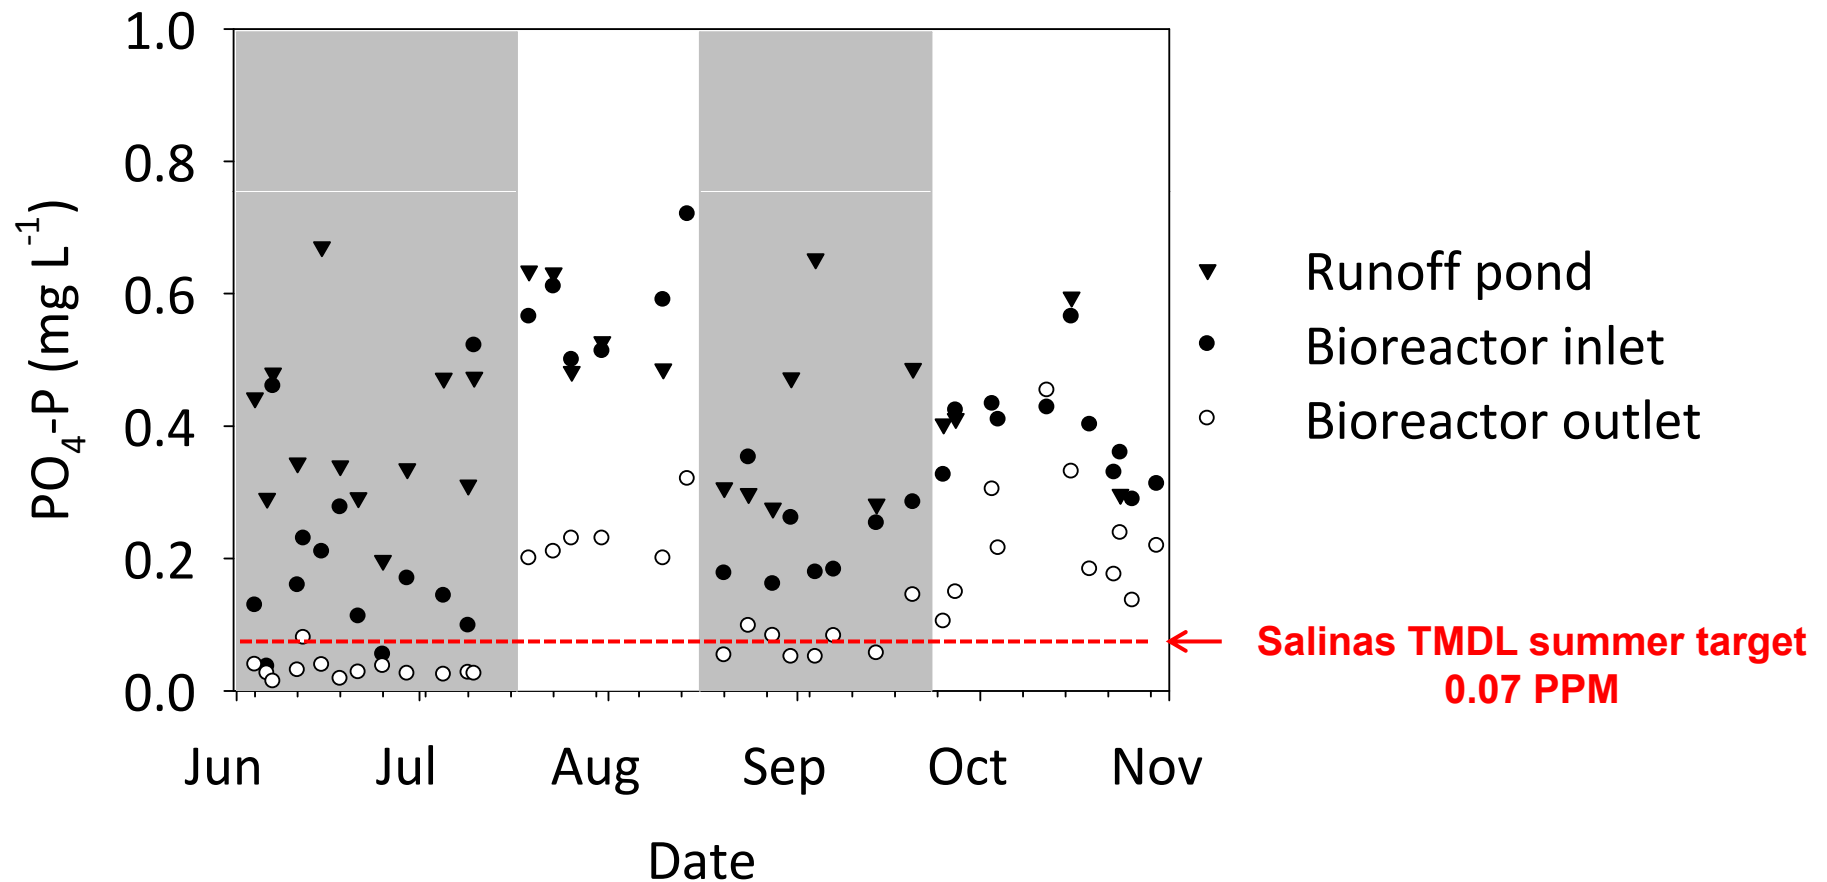

**Irrigation season average:
≈ 11-13 PPM $\text{NO}_3\text{-N}$ / day**

DBR performance on surface runoff :

What about PO₄-P ?

- Aluminum sulfate (alum) was injected during portions of 2012 (shaded area)

- Both alum and bioreactor treatment appear to remove PO₄-P

Are there environmental issues with DBRs ?

- **nitrous oxide (N_2O) release**
 - high per unit land area, small as a % of N denitrified
- **dissolved organic carbon (DOC) and tannins in DBR effluent**
 - effluent may need to be recycled on-farm in the initial weeks of operation

Are there microbial food safety implications?

- **No exposed water = no wildlife attraction**

Is a commercial scale DBR feasible ?

Based on a year-around operation:

- at an average of 6 PPM $\text{NO}_3\text{-N}$ removal per day of residence time, a DBR has the *theoretical* capacity to remove about 3 lb N / yd^3 of volume annually; *operational* capacity probably less
- under commercial conditions, a DBR 50 x 100 x 5 ft could probably remove at least 2,000 lb N annually
- costs are probably between \$1 - 4 per lb of $\text{NO}_3\text{-N}$ denitrified
- management practice changes would still be needed to come close to meeting environmental goals, particularly with tile drain effluent
