

Evaluation of Pre-plant & Post-plant Treatments for Replanted Peach Orchards

Roger Duncan

University of California Cooperative Extension,
Stanislaus County

Mike McKenry

Dept. of Nematology, UC Riverside

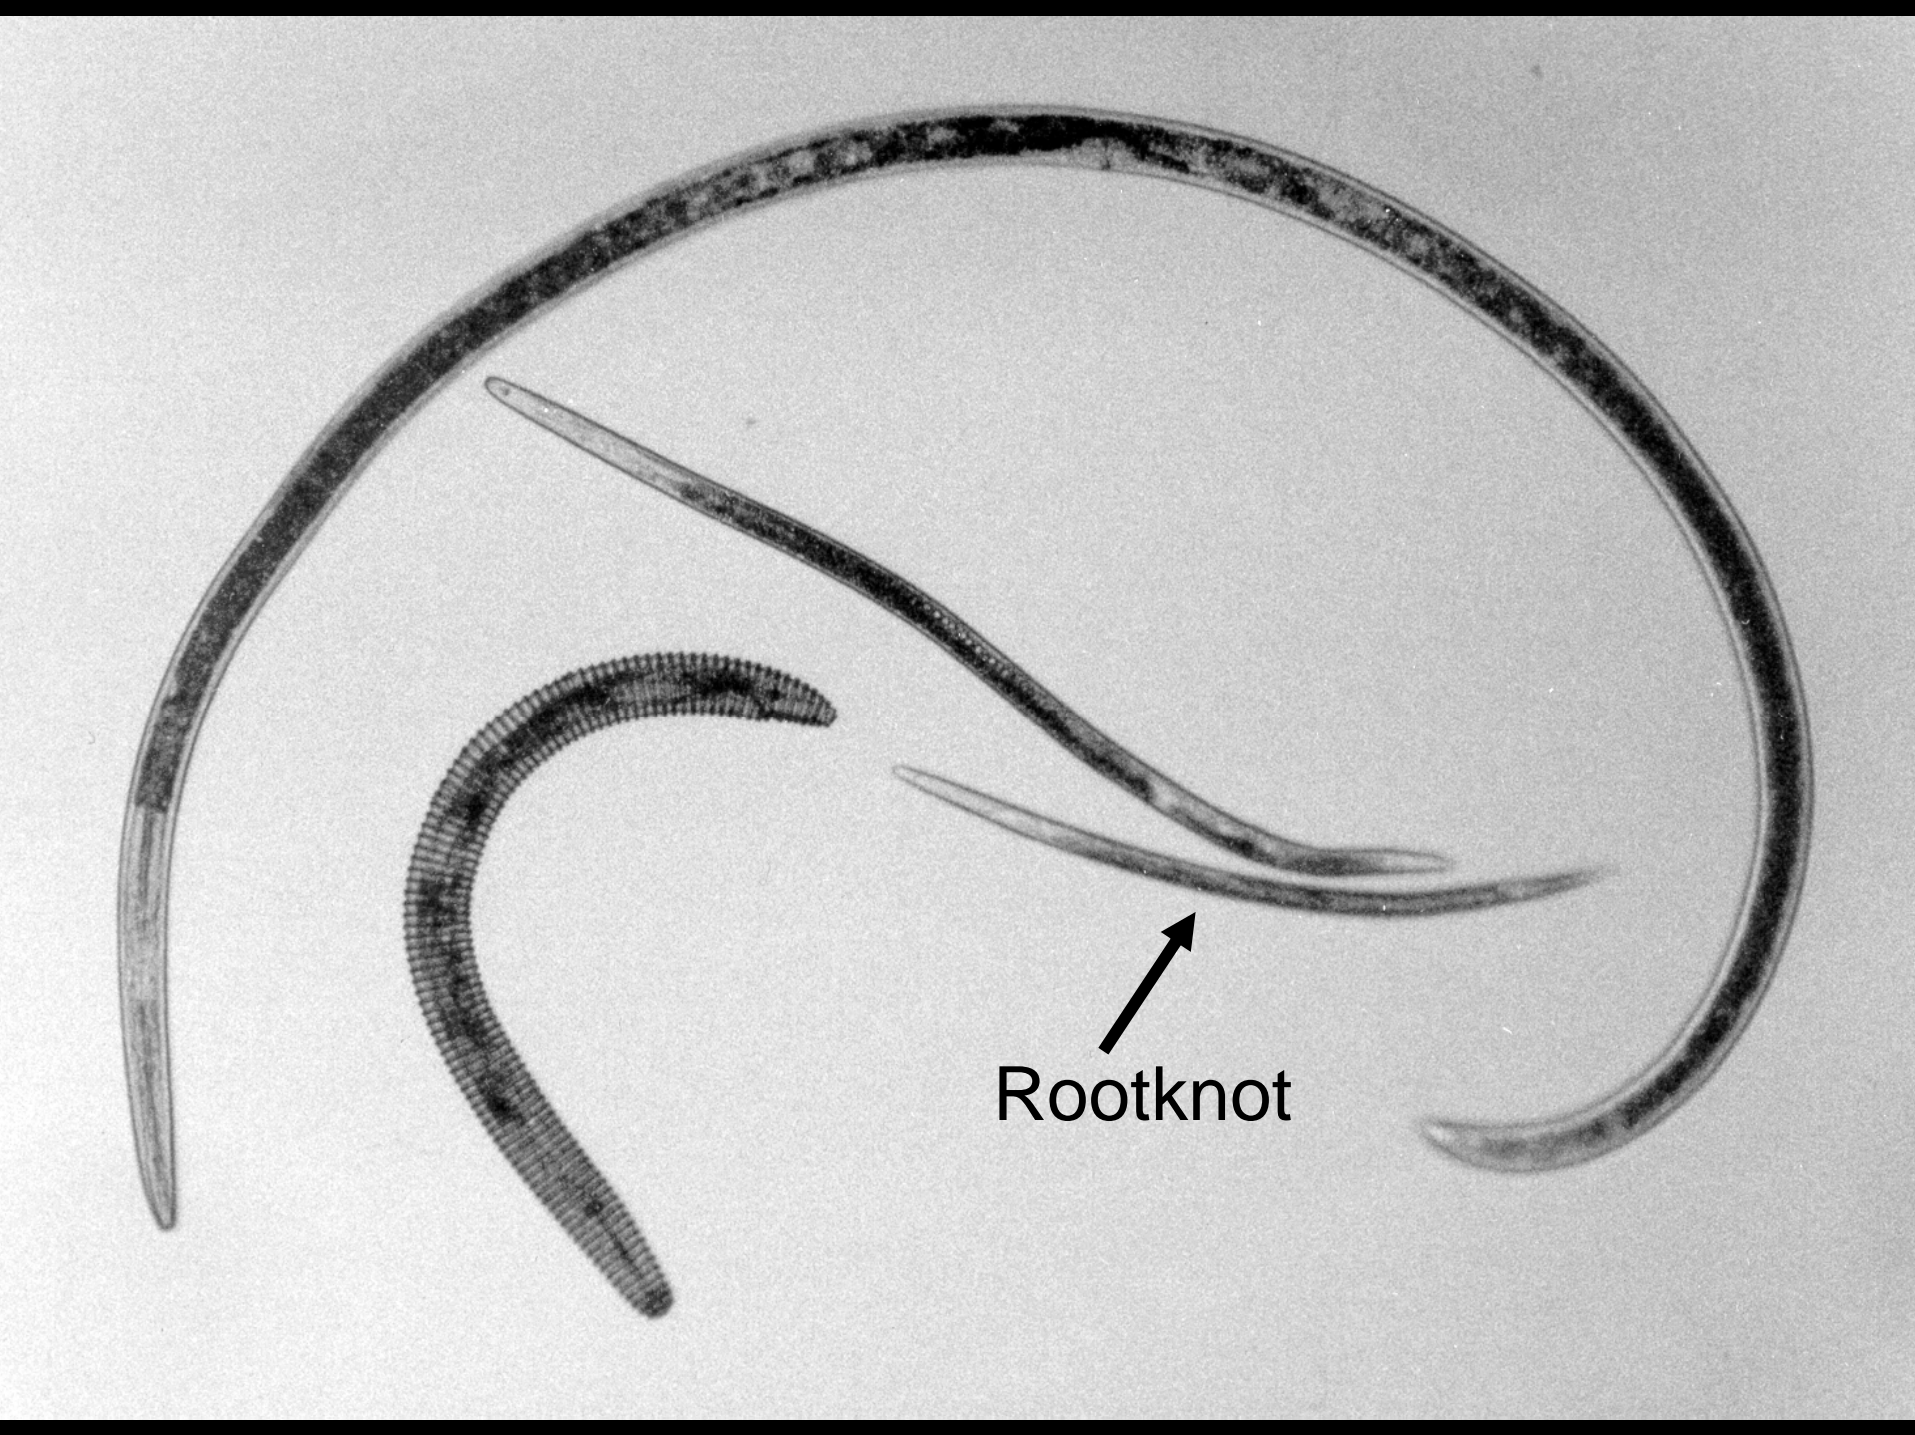

Kate Scow

Dept. of Land, Air & Water Resources, UC Davis

Second generation orchards do not grow as well because of...

- Nematodes
 - ring, root lesion (*P. vulnus*), root knot
- Poorly defined fungal / pathogenic microorganism complex
- Nutrient depletion

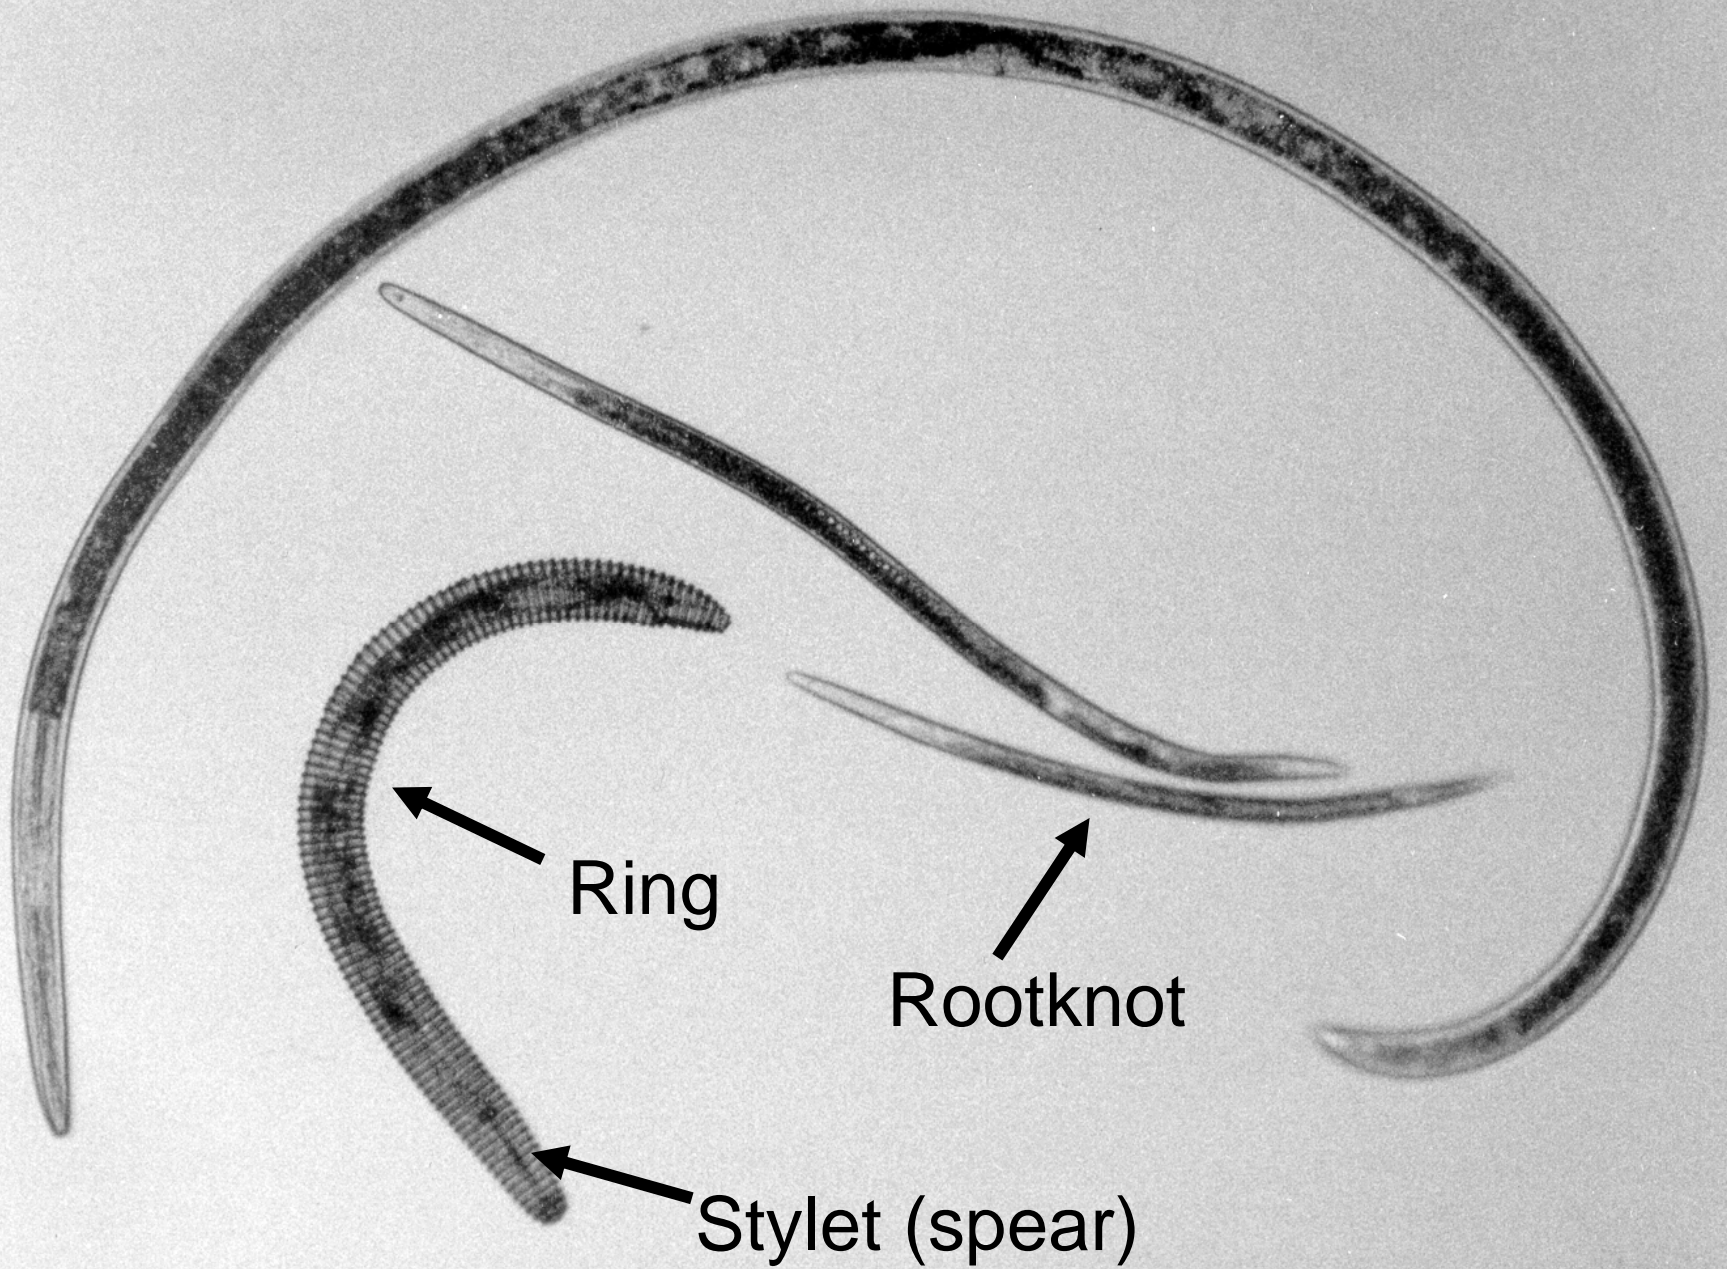

Rootknot

This image shows a microscopic view of a rootknot. The main feature is a large, thick-walled, curved structure, likely a giant cell, which is characteristic of rootknot disease. A smaller, segmented, curved structure is also visible, possibly representing a developing or mature stage of the parasite. An arrow points to the smaller structure, which is labeled 'Rootknot'.

How do we fix this?

■ Fumigation

- methyl bromide excellent fumigant
- addresses all three components of replant problem
- phased out??
- very expensive
- new regulations are very limiting

Questions:

- Can we use a combination of pre-plant and post-plant treatments to obtain results equal to, or better than, methyl bromide fumigation?
- What about microbiological soil amendments?

Cling Peach Replant Trial

Field location:

- Third generation peach orchard.
- Land fallow for two years prior to planting.
- Soil = loamy sand.
- History of bacterial canker.
- Moderate / high populations of ring and root lesion nematodes. One rep also has rootknot.

Cling Peach Replant Trial

■ Pre-plant treatments; October 2000

- Nonfumigated
- Methyl bromide tarped @ 400 lb per acre
- Vapam HL at 250 ppm (75 gpa) drenched
- *Telone II strip shanked @ 32 gpa. Telone applied to ~ 2 acres as observation only.

Applied East - West across rows

Solid, tarped fumigation with methyl bromide @ 400 lb per acre. Other strips treated with Vapam or left untreated. October, 2000

Cling Peach Replant Trial

Pre-plant treatments applied across rows (East - West).

Post-plant treatments applied down rows (North-South).

Allows for combination of pre-plant and post-plant treatments in a checkerboard design.

Cling Peach Replant Trial

Post-plant treatments

- **Enzone** @ 1000 ppm twice annually
 - **Nemacur 3** @ 1 gpa twice annually
 - **DiTera DF** @ 10 lb per acre twice annually
- Applied April & Oct.
2001, 2002, 2003
- **Additional N** (~50 lb fertigation, fall foliar with 100 lb urea)
 - **Composted green waste** & manure + **oyster shell flour** at planting, **Ca-12** injected 3X, foliar **CaCl** 3X
 - Compost & oyster shell + **Tilth**® & **Iota**® microbial amendments; 3 apps Apr, June, Sept.
 - Compost & shell + **humic acid**, **Shurcrop Supra**® kelp product, **Spectrum**® microbial amendment; 3 apps Apr, June, Sept.
 - **Black polyethylene** soil covering
 - Four annual sprays with **foliar micronutrients**

Application of compost to berms prior to planting.
January 2001

Some trees were dipped in kelp extract
and / or microbiological “cocktails”

Compost and oyster shell flour backfilled into planting hole.
February 2001.

First-leaf trees in treatment with black polyethylene mulch applied down tree row at planting.

| Control | 21.8 | 4.1 | \$1096 | -- |

Gross revenues based on 372.3 trees per acre and a price of \$270 per ton

Peach soil microbial community

- How do alternative fumigants and soil amendments alter soil microbial communities?
- How do soil microbial communities relate to plant performance?

Peach soil microbial community

- Carbon (compost) addition most important in shaping microbial community

- Microbial biomass higher in +C treatments, lowest in MB fumigated and mulched plots
- Microbial inoculants had no overall effect on community composition

Peach soil microbial community

- MB decreased biomass and certain functional groups
- Tree growth best in fumigated treatments
- Long term benefits of larger microbial community?

Lab and Field Test for Tissue Susceptibility to *Pseudomonas syringae*

| Urea | No | 27 c |
| Standard | Yes | 26 c |
| CaCl | Yes | 23 c |
| Urea | Yes | 20 c |

Conclusions

- Preplant fumigation eliminated more than 99% of the parasitic nematodes to a depth of at least 5 feet at planting time.
- After three seasons, there were significantly more ring nematodes in fumigated areas compared to nonfumigated.
- Nematicides applied annually knock nematodes down 50-75% but they quickly build back to pre-treatment levels in less than one year.

Conclusions

- Preplant fumigation has significantly increased plant growth and yield.
- MB increased gross revenue by \$4100 per acre in the first two harvests compared to nonfumigated.
- Vapam and Telone II increased gross revenue by about \$2100 and \$1800, respectively.

Conclusions

- Plastic mulch, foliar micronutrients and foliar nitrogen were the only post-plant treatments that increased yields in unfumigated areas.
- No post-plant treatment has increased yields in fumigated areas.
- We have seen no effects at all from microbiological amendments, kelp-based materials or humic acid treatments.

Conclusions

- Nitrogen fertilization significantly increased bark N%.
- Supplemental nitrogen fertilization significantly decreased peach susceptibility to BC in the presence of ring nematodes.
- Ca fertilization also reduced BC susceptibility, but not as much as N.

Conclusions

- Why haven't nematicides (applied annually for 3 years) resulted in increased yields??

Something other than nematodes is affecting tree performance.

Thank you for your
attention.

Questions??
