Pollen Storage

high viability of pollen obtained after storage in home freezer

W. H. Griggs, George H. Vansell, and Ben T. Iwakiri

Hundreds of samples of deciduous fruit and olive pollen—used in breeding and artificial pollination studies—have been stored satisfactorily from one season to the next in an ordinary home freezer at temperatures ranging close to 0° F.

Samples of both hand-collected and bee-collected pollen were kept in vials stoppered with cotton plugs, unsealed fruit jars, and woden boxes. No attempt was made to control humidity.

The table on this page shows examples of pollen germinability after extended periods of storage in the home freezer. The percentages of germination might have been higher if there had not been

a power failure which prevented the freezer from operating for four days.

Method

The germinability of the pollen samples was determined every two or three months by testing it on a plate of an agar-sugar medium consisting of 15% cane sugar and 2% agar. The pellet pollen collected by the honey bees was dispersed in a few drops of freshly prepared 15% cane sugar syrup at the time of plating. A smear was then made of the pollen-syrup mixture on the agar medium. Experience has shown that higher percentages of germination are obtained

Pollen Germination after Storage in a Home Freezer at Approximately 0° F (Storage Periods Were between March 3, 1950, and May 11, 1953)

when fresh agar media are prepared for each testing, and when lids are kept closed on the petri dishes containing the agarsugar medium and the germinating pollen to insure high humidity.

The success with which pollen was stored at temperatures far below freezing, indicates that the storage conditions for the various diverse species used by plant breeders may not be so specific as formerly believed. It further indicates that the storage life of many species might be greatly extended by temperatures ranging from those in home freezers down to those provided by dry ice.

The techniques of controlled or artificial pollination are no longer restricted to the research worker. Many orchardists are interested in the possibility of artificial pollination to insure a fruit set on self-unfruitful varieties which have been planted with inadequate facilities for cross-pollination.

Plant breeding has become an important profession and several commercial firms collect, cure, store, and sell various fruit pollens to be used in artificial pollination.

Results

Apple pollen from the pellets of pollencollecting honey bees gave high percentages of germination after 12 months in a dry ice container held at approximately -59.8° F during studies in 1950. The dry ice container was kept in an ordinary home freezer which was adjusted to maintain a temperature between 5° F and -2.2° F. Control samples in the freezer but not in the dry ice container—also maintained high germinability.

The ease with which pollen may be stored in the home freezer is advantageous since pollen storage at higher temperatures requires the maintenance of specific humidities and the use of either desiccators or other sealed containers.

Experimental work has been done to develop satisfactory methods of storing pollen to maintain high viability. Usually the studies considered the relation of pollen longevity to either temperature or humidity, or the interrelation of these factors. Pollen has most often been stored at temperatures ranging from 32° F to room temperature, and relative humidities have usually been maintained as either low or high. The low humidities have been attained with such drying agents as sulphuric acid or calcium chloride. Intermediate relative humidities between low and high have been attained with sulphuric acid-water mixtures.

W. H. Griggs is Assistant Professor of Pomology, University of California, Davis.

George H. Vansell is Entomologist, United States Department of Agriculture, Davis.

Ben T. Iwakiri is Senior Laboratory Technician, University of California, Davis.
