School-based physical activity interventions that include policy changes together with improving physical activity opportunities may be the most effective approach for improving student fitness

Background

The California Department of Public Health's (CDPH) CalFresh Healthy Living (CFHL) program is a substantial source of ongoing funding for nutrition education and obesity prevention in schools across the state. School-based physical activity interventions may be an effective way of improving youth cardiorespiratory fitness and health, especially at an age when establishing healthy behaviors is pivotal. Given the range of evidence-based interventions that are available to Local Health Departments (LHDs) to implement, researchers from Nutrition Policy Institute (NPI), CDPH, University of California Berkeley, and Arizona State University sought to understand which CFHL intervention combinations may be most effective in improving students’ fitness levels.

What We Evaluated

Utilizing secondary data from Fitnessgram and PEARs, this study aimed to:

- Identify and describe patterns of CFHL physical activity interventions implemented in CFHL-eligible CA public schools during Federal Fiscal Year 2016 (FFY16) (n=904 intervention schools, 93,716 students; 3,367 comparison schools; 349,027 students)
- Determine the association between identified intervention combinations and student VO2max the following school year (2016-17), to identify which intervention combinations are associated with the highest student VO2max values.

Latent class analysis (LCA), a type of modeling that identifies underlying subgroups within a population with shared characteristics, was used to categorize combinations of physical activity intervention components into intervention classes.

What is VO2Max? 4-6

The maximum volume (V) of oxygen (O2) effectively used by a person during exercise.

Influenced by physical activity habits, body composition, age, gender, and heredity.

Considered a reliable predictor of cardiovascular fitness and aerobic endurance.

Positively associated with lower risk of obesity and type 2 diabetes in young adulthood.

Funded by USDA SNAP, an equal opportunity provider and employer. Visit CalFreshHealthyLiving.org for healthy tips.
What We Found

Five intervention classes were identified:

1. **'Low on All' Schools**  
   \( n_{\text{schools}} = 569, n_{\text{students}} = 59,826 \)  
   - Low probabilities of doing any one CDPH-CFHL intervention component.

2. **'Policy Only' Schools**  
   \( n_{\text{schools}} = 203, n_{\text{students}} = 19,931 \)  
   - Established/improved school or district wellness policies and unlikely to implement any other type of intervention.

3. **'Policy & Physical Activity Opportunities' (PPAO) Schools**  
   \( n_{\text{schools}} = 58, n_{\text{students}} = 5,071 \)  
   - Established/improved wellness policies along with opportunities for physical activity.

4. **'Direct Education' Schools**  
   \( n_{\text{schools}} = 44, n_{\text{students}} = 6,367 \)  
   - High probabilities of providing direct education and very low probabilities of doing any other type of intervention.

5. **'Diverse PSEs' Schools**  
   \( n_{\text{schools}} = 30, n_{\text{students}} = 2,521 \)  
   - Somewhat likely to implement varied PSE strategies and unlikely to conduct direct or indirect education.

The 'Low On All' and 'Policy Only' intervention classes were the most common among intervention schools (63% and 22%), but also had the first and second lowest adjusted mean student \( VO_2 \text{max} \) values.

Only the 'PPAO' intervention class had a statistically significant association with student aerobic capacity but was one of the least commonly implemented intervention classes.

The adjusted average \( VO_2 \text{max} \) among 'PPAO school' students was greater than that of students attending...

- 'No Intervention' (comparison) (by 1.17 mL/kg/min)
- 'Direct Education' (by 0.70 mL/kg/min)
- 'Diverse PSEs' (by 0.94 mL/kg/min)
- 'Policy Only' (by 1.04 mL/kg/min)
- 'Low On All' (by 1.06 mL/kg/min)
Implications for CFHL Program Delivery and Future Research

This study found that students attending schools with interventions focused on improving both wellness policies and physical activity opportunities had, on average, greater aerobic capacity than students attending ‘no intervention’ (comparison) or other LCA class schools. These findings highlight:

Concentrating intervention efforts on both policy and physical activity opportunities may have a synergistic effect on improving and sustaining a school physical activity environment conducive to student health.

Working more intensely with schools to ensure effective intervention combinations are implemented and sustained may be more fruitful than expanding interventions to a greater number of schools if resources are limited.

Demographic differences between schools across LCA classes suggest that schools with greater percentages of students eligible for free and reduced-price meals, schools with greater percentages of Hispanic/Latinx students, and rural schools may benefit from more support for comprehensive physical activity interventions.
