Key Points of Control and Management of Microbial Food Safety: Information for Producers, Handlers, and Processors of Melons

TREVOR V. SUSLOW, UC Cooperative Extension Specialist, Department of Vegetable Crops, UC Davis.

Most fruits and vegetables eaten fresh in the United States are kept wholesome and free of microorganisms that could result in illness through the use of common and sensible handling and food preparation practices. In addition, many fruits and vegetables have natural barriers that minimize the chances that any surface contamination could be transferred to the internal, edible portions. A melon's rind is a good example of this natural packaging.

Contamination of the melon's outer surface by microbial pathogens can only result, ultimately, from an external environmental source. Contamination of the internal edible flesh is essentially limited to handling activities somewhere between harvest and plate. As with all fruits and vegetables that are eaten uncooked, the best approach to maintaining the wholesome nature and safe consumption of melons is to establish standard approaches that minimize the chances for external and internal contamination at every step. Proper preparation techniques, including washing the fruit, utensils, and cutting surfaces as well as refrigerating any fruit not consumed within 2 hours of cutting, should be followed by consumers and food service handlers (see ANR Publication 8095, Cantaloupe: Safe Methods to Store, Preserve, and Enjoy).

This publication provides a brief outline of the fundamental components of microbial food safety that should be part of any comprehensive management plan for melon producers, harvest service operators, distribution and wholesale handlers, and fresh cut processors. The diversity of environments, crop management practices, and handling practices make a single, universally applicable approach to food safety planning unrealistic. Instead, this quick reference guide will focus on the key guiding principles of *prevention of contamination*, *reduction of survival*, and *prevention of cross-contamination* for each step in melon commerce up to consumer handling. You can create your own food safety planning and management programs based on the application of these principles, which are the combined results of specific research and practical experience with cantaloupe and other melons.

Many of these same principles can be applied to planning for food security and the prevention of intentional food contamination. Helpful online resources in counterbioterrorism planning are listed at the end of this document.

BACKGROUND

Whether melons are produced domestically or imported, three key events have brought focus and concern for the microbial food safety of melons, particularly cantaloupes:

1. Recent and recurring disease outbreaks linked to cantaloupe consumption.
2. Positive detection and recovery of human pathogens from random samples of both imported and domestic cantaloupes.
3. Recent reports from several researchers indicating how difficult it is to clean and disinfect the netted rind of a cantaloupe.

For domestically produced cantaloupe, 3 percent of 164 melon samples in a recent check contained detectable *Salmonella* or *Shigella* bacteria (U.S. Food and Drug Administration, 2001). No melon samples from California were found to be positive for pathogen contamination.

At UC Davis, researchers have conducted an ongoing survey of cantaloupe produced in different regions of California, testing more than 1,600 field-collected melons since 1999. No *Salmonella* bacteria have been detected. Based on the overall level of cantaloupe consumption in the United States, the likelihood that a person will develop an illness that can be traced definitively to the contamination of fresh foods prior to food preparation is very low. It is equally clear, however, that disease outbreaks linked to cantaloupes from various production areas have occurred and that those outbreaks have affected large numbers of individuals across many states and into Canada. While most individuals can recover from a foodborne illness without any need for medical attention, some patients such as the very young, the very old, and those who may be otherwise immuno-compromised may suffer complications and even death.

WHAT ARE THE GUIDING PRINCIPLES OF FOOD SAFETY FOR FRESH PRODUCE?

- Once produce has been contaminated, removing or killing the pathogens is very difficult.
- Prevention of microbial contamination at all steps from production to distribution is strongly favored over treatments to eliminate contamination after it has occurred.
- Documentation of the implementation of prevention programs and food safety awareness training for workers at all levels of the agricultural and packing environments are key elements in a credible food safety program.

GUIDING PRINCIPLES FOR CROP PRODUCTION WATER

Wherever water comes into contact with fresh produce, its quality may directly determine the potential for persistent pathogen contamination.

- Become familiar with the routes and handling of surface water sources, seasonal influences on water quality, and any microbial monitoring programs followed by the supplier (for delivered water from public or private irrigation districts).
- Identify potential sources of contamination that could affect your water, especially those that are within your ability to control in a manner that would protect water quality.
- Ensure that wells are designed and maintained in a manner that prevents surface run-off and soil infiltration from contaminating the water supply.
- Water used for any foliar application should come from a pathogen-free source.
- Until more research data are available, we strongly recommend that any foliar applications within two weeks of harvest be from a potable water source.

GUIDING PRINCIPLES FOR MANURE AND MUNICIPAL BIOSOLIDS

Properly composted manures or municipal biosolids are not a source of microbial pathogens on fresh produce.

- Become informed about proper compost management for pathogen reduction, and document the methods used to eliminate pathogens from any manure that you apply.
- Document or obtain documentation about the specific compost management practices used for each lot.
- Maximize the time between the date you apply manure to production areas and the date you harvest those areas.
- In melon production areas where you use multi-season drip irrigation, the spreading of chicken manure or litter without incorporating it into the soil requires careful attention to ensure that pathogen reduction practices have been followed and documented.

GUIDING PRINCIPLES FOR MINIMIZING ANIMAL FECAL CONTAMINATION

It is not possible, or may not be permissible, to eliminate all animal influences from production fields. All the same, you need to determine what steps you can take to minimize their presence or activities.

- Domestic animals should be excluded from fields during the growing and harvesting season.
- Evaluate the need for bare soil buffers between your melon fields and adjacent land. Buffers can discourage the movement of reptiles, amphibians, and rodents—all potential sources of contamination—into your fields
- Minimize the presence of vector attractants (such as cull piles) within a production field.

GUIDING PRINCIPLES FOR WORKER HEALTH AND HYGIENE

There is no substitute for awareness, training, and constant reinforcement regarding the importance of each worker's personal hygiene and sanitation as critical elements in maintaining a sustainable business for you and continued employment for the worker.

- Follow all OSHA and CAL OSHA requirements for sanitary facilities.
- Establish a training program that includes proper hand washing techniques and the importance of using toilet facilities.
- Establish and communicate a clear policy that will allow workers who report or are observed to have symptoms of illness or diarrhea to be reassigned to paid activities that do not involve food or food surface contact. In the absence of such a policy, it is likely that workers will not report their illnesses for fear that they will lose wages.
- Carefully inspect areas that are frequented by unsupervised workers (such as night irrigators) for signs that additional training is needed.
- Provide bandages or other protective coverings to workers who have cuts or lesions that may make contact with fresh produce.

- If the workers use gloves, provide instruction on their proper use to prevent the transfer of pathogens to fresh produce.
- Use caution when servicing portable toilets to prevent leakage into a field.
- Provide physical diversion and containment in the event of waste spillage. Have a plan for how to isolate and destroy contaminated produce in the event of a spill.

GUIDING PRINCIPLES FOR FIELD AND HARVEST SANITATION

All surfaces and implements that touch fresh produce must be treated as food contact surfaces.

- Clean all food contact surfaces and harvest containers or bins prior to use.
- Ensure that harvest contractors and crews are aware of the principles of microbial food safety risk reduction and that they adhere to established food safety practices.
- Develop and document a system of cleaning and sanitizing food contact surfaces.
- Minimize the opportunity for disease vectors (rodents, birds, flies, reptiles, and amphibians) to contaminate packing surfaces and materials.
- Minimize vectors' access or attraction to harvest equipment kept in the field (for instance, do not leave damaged fruit or heavy juice residue on belts or grading tables).

GUIDING PRINCIPLES FOR PACKING FACILITIES

Well-designed and operated centralized packing facilities and packing systems have the potential to contribute to the reduction of pathogen contamination. Management lapses in facilities or systems have the potential to amplify any localized contamination, broadly redistribute pathogens, or create opportunities for pathogen contamination within the facility.

- Design and maintain packing surfaces and equipment to minimize injury to the produce and to maximize accessibility for cleaning or sanitizing.
- Establish routine cleaning and sanitizing programs for all food contact surfaces.
- Remove as much dirt as is practical from harvest containers, trailers, or gondolas between harvest uses. This should be done outside of the packing facility, away from any water source that is used for postharvest handling.
- Clean pallets, containers, or bins before use.
- Establish and maintain a pest control program.
- Prevent birds and other vectors from contaminating packing equipment surfaces, packing areas, and storage areas.
- Store unformed or empty containers off the floor or bare soil surface and in a way that protects them from contamination.

GUIDING PRINCIPLES FOR POSTHARVEST WATER DURING PACKING

The quality of the water that contacts fresh produce during postharvest cleaning, grading, cooling, and surface treatment application is widely recognized as the essential pathogen control point for fresh produce.

- Follow programs typical of Good Manufacturing Practices (GMP) to ensure that all water is of adequate quality throughout all packing operations from start-up to the last packed unit.

- Antimicrobial chemicals help minimize the potential for microbial contamination to spread in packing operation water; levels of antimicrobial chemicals must be routinely monitored and recorded to ensure they stay at appropriate levels.
- Special attention to water quality is required for dump tank systems and recirculated water.
- Keep air-cooling and chilling equipment clean and sanitary.
- Transport, store, and use ice under sanitary conditions.

GUIDING PRINCIPLES FOR TRANSPORTATION

Limited control is possible beyond the shipping dock, but the consequences of cross-contamination during transportation and distribution will be linked back to the handler and grower.

- Inspect transportation vehicles for cleanliness, odors, and obvious dirt and debris before loading. If necessary, insist that trailers or containers be cleaned out before loading.
- Ensure that transporters, distributors, and retailers maintain the integrity of the positive lot identification and traceback systems that have been implemented by the melon industry.

GUIDING PRINCIPLES FOR STORAGE AND DISTRIBUTION

Well-designed and operated wholesale distribution, load consolidation, and cross-docking facilities have the potential to maintain the integrity of a pathogen-free product. Lapses in facility sanitation or system management have the potential to amplify localized contamination, promote internalization of pathogens into products, and broadly redistribute pathogens.

Mixed storage and mixed load distribution have the potential to transfer contamination from one lot or product to another that was not previously contaminated, especially where pallet-stacking, ice injection, or top-icing is involved.

- Be aware of the potential for cross-contamination.
- Separate dry and wet products and place water-repellent shipping barriers between commodities in mixed loads.

GUIDING PRINCIPLES FOR FRESH CUT OR VALUE-ADDED PROCESSING

Well-designed and operated processing facilities have the potential to contribute to the reduction of pathogen contamination. Lapses in facility or system management have the potential to amplify localized contamination, broadly redistribute pathogens to the edible flesh, or contaminate pathogen-free melons from within the facility during handling.

The exterior of a cantaloupe is more difficult to clean than the exterior of smooth, waxy melons such as honeydew and watermelon. Mechanical cleaning with brushing in combination with an approved antimicrobial agent is essential before the rind is cut and removed.

Proper temperature management (cold chain control) is important for quality and safety management, but you cannot rely upon it alone to provide sufficient consumer protection from the potential of foodborne illness.

- Use only good quality fruit, free from open wounds or defects that may have allowed bacteria to become internalized. Avoid fruit that have visible sunken areas or areas of mold or decay.
- Product flow should be linear; incoming product should not cross paths or be stored next to cleaned or processed product. Ideally, packing areas should be physically separated from receiving and processing areas.
- Worker traffic flow and activities should not move between packing and receiving.
- Develop specific worker training programs for fruit handling and processing to prevent bare-hand or gloved-hand contact with uncleaned fruit rind and cut fruit flesh, in sequence, by the same individual.
- Antimicrobial chemicals help minimize the potential for microbial contamination to be spread by process water; levels of antimicrobial chemicals must be routinely monitored and recorded to ensure they are maintained at appropriate levels.
- Special attention to water quality is required for common wash tank or flume systems and any recirculated water.
