Cancer therapy is a double-edged sword, as surgery and chemotherapy can induce an inflammatory/immunosuppressive injury response that promotes dormancy escape and tumor recurrence. We hypothesized that these events could be altered by early blockade of the inflammatory cascade and/or by accelerating the resolution of inflammation. Preoperative, but not postoperative, administration of the nonsteroidal antiinflammatory drug ketorolac and/or resolvins, a family of specialized proresolving autacoid mediators, eliminated micrometastases in multiple tumor-resection models, resulting in long-term survival. Ketaolac unleashed anticancer T cell immunity that was augmented by immune checkpoint blockade, negated by adjuvant chemotherapy, and dependent on inhibition of the CDX-1/thromboxane A₂ (TXA₂) pathway. Preoperative stimulation of inflammation resolution via resolvins (RvD2, RvD3, and RvD4) inhibited metastases and induced T cell responses. Ketorolac and resolvins exhibited synergistic antitumor activity and prevented surgery- or chemotherapy-induced dormancy escape. Thus, simultaneously blocking the ensuing proinflammatory response and activating endogenous resolution programs before surgery may eliminate micrometastases and reduce tumor recurrence.

Introduction
Cancer treatment is a double-edged sword, as surgery (including biopsy), chemotherapy, or radiation can induce tumor-dormancy escape and subsequent metastatic outgrowth by impairing tumor-specific immunity through inflammation-mediated growth signals and loss of resolution of inflammation (1–16). Even anesthetics can impair inflammation resolution (17). Recent results show that chemotherapy-generated cell death can paradoxically promote tumor growth via the release of proinflammatory and proangiogenic cytokines (9, 10, 18). Moreover, a preoperative cycle of chemotherapy can stimulate proinflammatory cytokines after cancer surgery (19), and surgical wounding may impair the efficacy of chemotherapy (20).

In the treatment of locoregional disease, the perioperative period offers a unique window for curbing the risk of metastatic growth and relapse (2, 4, 21–27). For instance, a bimodal pattern of recurrence for early stage breast and lung cancers suggests that surgery potentiates the metastatic process by inducing tumor-dormancy escape of micrometastatic lesions (28–30). Micrometastases present in cancer patients at the time of surgery are associated with reduced survival (31). Moreover, surgery can promote metastasis, not simply by mechanical dissemination of cancer cells, but also by stimulation of systemic inflammation and surgery-associated immunosuppression, resulting in outgrowth of dormant cancer cells at distant sites (2).

Over 30% of healthy individuals harbor microscopic dormant cancers (32), and noncancer surgery and anesthesia may promote the growth of such occult microtumors (33). Importantly, retrospective analyses of tumor recurrence in patients undergoing breast cancer surgery revealed that preoperative administration of ketorolac
was associated with a marked reduction of recurrence and mortality after surgery (34). However, ketorolac did not exhibit cancer-preventive activity when administered postoperatively, which is when NSAIDs are routinely administered for pain management (34). Preoperative ketorolac increased blood CD4+ T cells in patients undergoing tumor resection, potentially reversing surgery-induced immunosuppression during the perioperative period (35).

Chronic inflammation has been associated with tumor-promoting activity (36, 37), in part due to a deficit in the resolution of inflammation (12). Cancer therapies have focused on blocking the production of COX-2-derived eicosanoids to suppress tumor-promoting inflammation (38). However, COX-2 is also host protective, as its metabolite, prostaglandin E\(_2\) (PGE\(_2\)), plays a role in the resolution of inflammation in the chronic phase (39). Specifically, tight regulation of the temporal pattern of PGE\(_2\) release is critical for activating the class switching of lipid mediators from production of inflammatory mediators to that of proresolution signals through specialized proresolving mediators (SPMs) (40, 41). PGE\(_2\), released by dead cells negatively regulates an inflammatory response activated by damage-associated molecular patterns, which may also contribute to the proresolution activity of PGE\(_2\) (42). Other COX-2-derived prostaglandins of the D2 and J2 series generate lipid mediators that accelerate resolution of inflammation and control endogenous inflammation (12). Thus, COX-2 inhibitors may be “resolution toxic,” as they suppress the production of these prostaglandins (12, 39, 40, 43) and may worsen therapy-induced cancer progression.

PGE\(_2\), also exhibits immunosuppressive activity, stimulates regulatory T cells, inhibits antigen presentation, and suppresses NK cells (36, 38). Although these functions demonstrate the role of PGE\(_2\) in the resolution phase of inflammation, they may inhibit antitumor immunity, hence promoting tumor escape (36). The dual activities of eicosanoids may explain the biphasic dose-dependent or paradoxical relationship between chronic use of NSAIDs and cancer risk (44). Given the opposing roles of eicosanoids, NSAIDs that are intended to block tumor-promoting inflammation may counter the resolution process and thus impose an inherent limitation of efficacy. Thus, simultaneously blocking the proinflammatory response and activating endogenous resolution programs may control cancer therapy–stimulated inflammation.

The SPM superfamily consists of potent immunoresolvent agonists derived from omega-3 fatty acids (e.g., resolvins, protectins, and maresins) as well as arachidonic acid (e.g., lipoxins) (12, 43, 45–47). Resolvins, lipoxins, and aspirin-triggered SPMs exhibit antitumor activity by promoting the clearance of therapy-generated tumor cell debris and counterregulating proinflammatory cytokines (9, 48–51). Interestingly, unlike other synthetic nontoxic NSAIDs, aspirin irreversibly acetylates COX-2 and converts its enzymatic activity to produce aspirin-triggered SPMs. Thus, aspirin’s mechanism of action involves both inhibition of proinflammatory mediators and stimulation of proresolving mediators (12, 51).

Here, we utilize a well-established animal model in which dormancy escape and outgrowth of lung metastases are triggered by primary tumor resection to study therapeutic approaches to overcoming the tumor-promoting capability of surgery. We show that a single preoperative, but not postoperative, dose of ketorolac suppresses lung micrometastases present at the time of primary tumor resection, an outcome dependent on COX-2 activity and host antitumor immunity as well as inhibition of COX-1–derived thromboxane A\(_2\) (TXA\(_2\)). Moreover, preoperative acceleration of inflammation resolution with resolvins inhibited micrometastases and prevented tumor-dormancy escape. Our results indicate that preoperative and perichemotherapeutic interventions can control tumor recurrence via inflammation resolution and promotion of host antitumor immunity.

**Results**

*Preoperative ketorolac eradicates micrometastases and promotes long-term survival in multiple tumor-resection models.* To investigate whether preoperative ketorolac affects survival in tumor-resection models, we utilized a metastatic lung cancer model in which primary syngeneic Lewis lung carcinoma (LLC) tumors were grown to 1500–2000 mm\(^3\) in male C57BL/6J mice, resulting in micrometastases at the time of tumor resection (9, 52, 53). Following resection of primary tumors, control mice reproducibly succumbed to lung metastasis by day 24 after resection (Figure 1A). While 60% of mice administered preoperative ketorolac expired from macroscopic lung metastases by day 43, the remaining 40% exhibited long-term survival (defined as >90 days after tumor resection). In contrast, postoperative ketorolac did not prolong survival compared with that of control animals, as all postoperative ketorolactreated mice were moribund from spontaneous lung metastasis by day 25 after resection (Figure 1A).

H&E staining revealed abundant micrometastases throughout the lungs at the time of LLC resection (day 0) (Figure 1B). Micrometastases were also detected at 7 days after LLC resection in approximately 60% of ketorolac-treated mice (Supplemental Figure 1A; supplemental material available online with this article; https://doi.org/10.1172/JCI127282DS1). In contrast, no micrometastases were detected in lungs from preoperative ketorolac-treated long-term survivors (day 240) (Figure 1B). We conducted similar experiments in the highly invasive E0771 and orthotopic 4T1 breast cancer models, which metastasize to the lungs (54). Preoperative ketorolac resulted in long-term survival in 30% of mice at 240 days after resection compared with control mice in the E0771 model (Supplemental Figure 1B). In an orthotopic 4T1 breast cancer model in female BALB/cj mice, preoperative ketorolac resulted in sustained survival in 40% of these mice after mastectomy (Supplemental Figure 1C). Thus, the antitumor activity of preoperative ketorolac is independent of tumor type, sex, strain, or location of the primary tumor.

*Ketorolac prevents surgery- and chemotherapy-induced tumor dormancy escape.* Systemic tumor recurrence after primary tumor resection can result from stimulation of dormant micrometastases present at the time of surgery (1, 2, 52), tumor cell dissemination during surgery (1, 55), or de novo tumorigenesis. To determine whether ketorolac can suppress surgery- or chemotherapy-induced tumor-dormancy escape, we utilized nonresection models in which mice are injected with a subthreshold (nontumorigenic) inoculum of 10\(^4\) LLC, 10\(^4\) EL4 (lymphoma), or 10\(^3\) B16F10 (melanoma) tumor cells. Despite the presence of tumor cells, mice in this model can survive for over 200 days without evidence of progressive tumor growth, thereby mimicking tumor dormancy and minimal residual disease (9, 53, 56). Consistent with surgery-stimulated tumor growth (1–4), laparotomy performed distant from the primary
While chemotherapeutic agents can suppress growth of established tumors, they can paradoxically stimulate the growth of a subthreshold inoculum of the identical tumor type (9, 18). Peri-chemotherapeutic administration of ketorolac neutralized chemotherapy-stimulated tumor growth in mice injected with a subthreshold inoculum of 10^4 tumor cells, including cisplatin-stimulated LLC, vincristine-stimulated EL4, and 5-fluorouracil–stimulated (5-FU–stimulated) CT26 (colon carcinoma) (Figure 1, F–H). However, GFP-labeled tumor cells were detected at the tumor implantation site when ketorolac was administered with cisplatin to mice bearing LLC-GFP tumors (Supplemental Figure 1F). Thus, ketorolac inhibited both surgery- and chemotherapy-induced tumor-dormancy escape.
COX-1 inhibition and basal COX-2 activity are critical for the antitumor activity of ketorolac. Among the FDA-approved NSAIDs, ketorolac preferentially inhibits COX-1 and exhibits lower COX-2 activity (57, 58). To determine whether the observed antitumor activity of preoperative ketorolac was mediated by COX-1 and/or COX-2 inhibition, we utilized 3 highly selective COX-1 inhibitors (SC-560, FR122047, or TFAP), the selective COX-2 inhibitor celecoxib, and the nonselective COX inhibitor indomethacin (38, 59). Similar to ketorolac, preoperative administration of the selective COX-1 inhibitors resulted in long-term survival in 40%-50% of mice up to 230 days after LLC resection (Figure 2A). However, celecoxib did not result in sustained survival (Figure 2B), suggesting that the observed antitumor activity of ketorolac is likely mediated by COX-1 inhibition.

Although indomethacin prolonged survival compared with control, no long-term survivors after LLC resection were noted (Figure 2A). A similar response profile of antitumor activity was observed with other nonselective NSAIDs, such as diclofenac, ibuprofen, and high-dose aspirin (30 mg/kg) (Figure 2B). Aspirin can prevent metastasis by inhibiting COX-1 activity and subsequent TXA2 synthesis (60, 61). Low-dose aspirin prolonged survival compared with high-dose aspirin (which engenders more complete inhibition of COX-2) (Figure 2B), suggesting that preoperative COX-2 inhibition may negate the anticancer activity of ketorolac. Indeed, preoperative coadministration of celecoxib and ketorolac resulted in no long-term survivors (Figure 2C). To confirm that COX-2 inhibition may impair the activity of preoperative ketorolac, we next performed the LLC tumor-resection experiments in COX-2–KO mice. While preoperative ketorolac resulted in long-term survival after resection in WT mice, long-term survival was not observed in COX-2–KO mice (Figure 2D). Moreover, the combination of preoperative ketorolac and an anti-PGE2 neutralizing antibody did not result in any long-term survivors after resection (Figure 2E). Therefore, in the LLC tumor-resection model, baseline COX-2 activity and PGE2 levels may be necessary for the antitumor activity of ketorolac.

Since COX-1 preferentially mediates TXA2 production (38, 61), we measured plasma TXB2, a stable hydration product of TXA2 used to assess COX-1 activity. Profiling based on liquid chromatography–tandem mass spectrometry (LC-MS/MS) revealed dramatic reduction of TXB2 at 2 hours after LLC resection as well as a lesser reduction in PGE2 in ketorolac-treated mice compared with control (Figure 3, A and B). To ascertain a functional role for TXA2 in the observed antitumor activity of ketorolac, we performed primary tumor resections in mice lacking the thromboxane prostanoid (TP) receptor. TP-KO mice exhibited long-term survival compared with WT mice (Figure 3C). Moreover, the combination of preoperative ketorolac and an anti-PGE2 neutralizing antibody did not result in any long-term survivors after resection (Figure 2E). Therefore, in the LLC tumor-resection model, baseline COX-2 activity and PGE2 levels may be necessary for the antitumor activity of ketorolac.
Supplemental Figure 2). This broad lipidomic shift indicates a complex balance between pro- and antitumorigenic mediators (53), which may account for the observed subset of ketorolac-treated mice that developed invasive lung metastasis (Figure 1A). Notably, lipoxin A4 (LXA4) was increased in the plasma of preoperative ketorolac-treated mice after LLC resection (Figure 4A). Since LXA4 is an SPM (12), we reasoned that the balance of inflammation regulation may be tipped toward resolution, thereby either enhancing or recapitulating the antiinflammatory and proresolving activity of ketorolac. Indeed, SPMs, such as lipoxins and resolvins, possess potent antitumor activity in experimental models (9, 48–51, 62).

To determine whether stimulation of inflammation resolution could prevent tumor recurrence and/or suppress outgrowth of micrometastases, we administered resolvins via osmotic pump 2 hours prior to tumor resection. Preoperative resolvin D2 (RvD2) prolonged survival after tumor resection and was more potent in preventing metastasis than RvD2 administered at the time of surgery (Figure 4B). Specifically, preoperative administration of resolvins (RvD2, RvD3, or RvD4) resulted in 50%–80% survival at 37 days after resection, with RvD2 exhibiting the most potent antitumor activity (Figure 4C).

Since low-dose aspirin triggers the production of resolvins from omega-3 fatty acids (12), we treated mice with low-dose aspirin in combination with an omega-3 fatty acid diet and found increased survival, but no long-term survivors (Figure 4D). Although aspirin
or omega-3 fatty acid diet alone exhibited less antitumor activity than the combination treatment, survival was prolonged compared with that of mice fed an omega-6 fatty acid diet. The omega-6 fatty acid diet alone accelerated progression and shortened median survival in mice from 19 days (control, Figure 2, A and B) to 16 days (Figure 4E) after resection, consistent with studies suggesting that dietary omega-6 fatty acids can promote tumor progression and metastasis (53). Moreover, the omega-6 fatty acid diet alone markedly shortened survival compared with combinations with aspirin, RvD2, and/or ketorolac (Figure 4E).

The potent antitumor activity of low-dose aspirin combined with omega-3 fatty acids offered the opportunity to examine whether promotion of resolution of inflammation could synergize with the antiinflammatory activity of ketorolac. Intriguingly, preoperative ketorolac in combination with low-dose aspirin and omega-3 fatty acid diet resulted in 90% survival at 110 days after resection (Figure 4D). The combination of preoperative ketorolac and resolvins led to long-term survival after resection in 70% of mice administered the omega-6 fatty acid diet (Figure 4E). Tumor cells were undetectable in H&E-stained sections of lungs from long-term survivors treated with preoperative RvD2 or the combination of low-dose aspirin, omega-3 fatty acid diet and ketorolac (day 180) (Figure 4, F and G).

To determine whether the antitumor activity of resolvins extended to a surgery-induced tumor-dormancy escape model, we injected $10^4$ EL4 into mice and performed a laparotomy, which triggered dramatic tumor outgrowth. Preoperative RvD2 prevent-
ed surgery-induced EL4 tumor-dormancy escape (Figure 4H). Thus, preoperative stimulation of inflammation resolution with resolvins may inhibit surgery-induced tumor recurrence.

**The antitumor activity of ketorolac is T cell dependent and impaired by chemotherapy.** Inflammation plays a multifaceted role in regulating the adaptive immune response. For example, prostaglandins, such as PGE$_2$, suppress acute inflammatory mediators, activate dendritic cells, sensitize T cells to eliminate infection, and promote T cell exhaustion (36, 42). Moreover, adaptive antitumor immunity has been implicated in the regulation of metastatic tumor dormancy (63, 64). These facts, along with the absence of tumor cells in the lungs of long-term survivors, led us to examine whether the immune system...
plays a role in the antitumor activity of ketorolac. Preoperative ketorolac prolonged survival in 60% of immunocompetent C57BL/6J mice up to 120 days after LLC resection (Figure 5A). In contrast, ketorolac did not improve survival after resection in SCID mice, which lack functional B and T lymphocytes (Figure 5A). SCID mice exhibited a drastically shortened baseline survival in the LLC tumor-resection model, with a median overall survival of 10 days compared with 25 days in C57BL/6J mice (Figure 5A). Similarly, ketorolac did not affect laparotomy-induced tumor-dormancy escape in immunodeficient SCID or RAG1-KO mice (Figure 5, B and C).

To investigate the specific role of T cells in the antitumor activity of ketorolac, we utilized nude athymic mice in a C57BL/6J background. The antitumor activity of ketorolac was abrogated in these mice, as all of the ketorolac-treated mice succumbed to lung metastasis by day 22 after LLC resection (Figure 5D). To confirm that the observed antitumor activity of ketorolac was T cell mediated, we depleted CD8+ and/or CD4+ T cells in vivo using neutralizing antibodies. T cell depletion of either subtype abolished the antitumor activity of ketorolac (Figure 5E), confirming that both T cell subtypes are necessary for the ketorolac-induced antitumor response. Immunohistochemistry revealed increased CD8+ and CD4+ T lymphocytes and decreased cells positive for the regulatory T cell marker FOXP3 in the spleen and lung tissues of ketorolac-treated mice on days 5 and 7 after resection, respectively, as compared with control mice (Figure 5F and Supplemental Figure 3A). RvD2 also increased CD8+ T lymphocytes in the lung tissues of mice (day 180 after resection) (Supplemental Figure 3B).

Therefore, the antitumor activity of ketorolac and resolvins may be mediated by activation of CD4+ and/or CD8+ T cells. Since checkpoint inhibitors such as anti-programmed cell death protein 1 (anti-PD1) antibody can augment cytolytic T cell responses, we hypothesized that preoperative ketorolac and immune-checkpoint blockade may act synergistically in our resection models. Indeed, this combination resulted in synergistic antitumor activity, with approximately 80% of animals exhibiting long-term survival in both syngeneic LLC and EL4 tumor-resection models (Figure 6, A and B). While ketorolac alone exhibited antitumor activity that was further enhanced by anti-PD1 treat-
100 days after injection. When these mice were injected with a second syngeneic tumor type (10^6 B16F10), they exhibited rapid tumor growth (Figure 6D), suggesting tumor-specific immunity. Similarly, preoperative ketorolac-treated long-term survivors in the postlaparotomy and postchemotherapy LLC tumor-dormancy escape models were resistant to LLC challenge, but exhibited rapid tumor growth when challenged with B16F10 tumor cells (Supplemental Figure 4, A and B). Moreover, preoperative RvD2-treated long-term survivors after LLC resection were also resistant to LLC rechallenge for over 100 days after injection. When these mice were injected with a second syngeneic tumor type (10^6 B16F10), they exhibited rapid tumor growth (Figure 6D), suggesting tumor-specific immunity. Similarly, preoperative ketorolac-treated long-term survivors in the postlaparotomy and postchemotherapy LLC tumor-dormancy escape models were resistant to LLC challenge, but exhibited rapid tumor growth when challenged with B16F10 tumor cells (Supplemental Figure 4, A and B). Moreover, preoperative RvD2-treated long-term survivors after LLC resection were also resistant to LLC rechallenge for over

Figure 7. ScRNA-Seq analysis demonstrates an altered immune landscape in response to ketorolac. ScRNA-Seq analysis on splenic cells isolated from preoperative ketorolac-treated or control mice 7 days after LLC resection. n = 2 mice/group throughout. (A) 2D visualization of single-cell clusters generated using the TSNE approach from normalized data of 2429 ketorolac-treated and 1864 control splenic cells. Cell clusters were annotated based on expression of established immune cell markers, e.g., T cells (Cd3d^+), exhausted T cells (Pdcd1, Ctl4a, Lag3, Entpd1, and TIM3), T memory cells (il7r, Ccr7, Sell, CD44), B cells (Cd19^+), dendritic cells (Itgax), and macrophages (Adgre1) (left panel). Chart depicts relative proportions of cells in the clusters from each sample (right panel). (B) Percentage of cells from control and ketorolac-treated mice, per cluster. (C) Preoperative ketorolac effects on the immune landscape of T cells. Feature maps depict the expression of T cell (Cd3d^+), exhausted T cell (Pdcd1), and memory T cell (il7r) markers for each cell cluster on the TSNE map. Cells from ketorolac-treated and control samples are shown as solid dots and triangles, respectively. Bar plots depict the relative proportions of T cell subpopulations in control and ketorolac-treated single-cell profiles. (D) Heatmap depicts the activation or inhibition of key regulators in the control and ketorolac-treated T cell clusters. Regulators were calculated based on Z scores using an upstream regulator analysis module in ingenuity pathways analysis systems.
Cancer patients undergoing tumor resection often receive adjuvant chemotherapy, as perioperative chemotherapy may be most effective when administered before surgery, at the time of surgery or soon after surgery (65, 66). Thus, we determined whether administration of chemotherapy after preoperative ketorolac would affect survival and antitumor immunity after tumor resection. A single dose of cisplatin on day 7 after LLC resection abrogated the long-term survival observed in the preoperative ketorolac group (Supplemental Figure 6A). Immunohistochemistry revealed that chemotherapy following preoperative ketorolac reduced the number of CD4+ and CD8+ T cells compared with preoperative ketorolac alone on day 7 after LLC resection (Supplemental Figure 6B). Adjuvant chemotherapy is typically administered 4 to 6 weeks after surgery. We therefore asked whether delayed administration of chemotherapy would also influence preoperative ketorolac-treated long-term survivors. Ketorolac-treated mice surviving over 90 days after LLC resection were subjected to 3 cycles of cisplatin (5 mg/kg q 5 days) and then rechallenged with LLC tumor cells. This challenge resulted in a rapid onset of LLC tumor growth in the ketorolac-treated as well as control mice (Supplemental Figure 6C). Therefore, adjuvant chemotherapy, even when administered a few weeks after tumor resection, may interfere with the antitumor immunity of preoperative ketorolac.

Figure 8. Key regulators in granulocytes/neutrophils from preoperative ketorolac-treated and control mice. Spleens from preoperative ketorolac-treated and control mice are identical to those used in Figure 7. (A) Feature and bar plots highlight the proportion of Ly6g+ and Mmp9-producing granulocytes/neutrophils in spleens from ketorolac-treated or control mice. (B) Interactive network of key regulators significantly activated in granulocytes/neutrophils from control mice. Bar graph depicts Z score (>1.5 = activation, <1.5 = inhibition) of NF-κB and PI3K complexes in control and ketorolac-treated samples based on expression of genes in the granulocyte/neutrophil cluster.

80 days after injection, yet developed aggressive tumor growth when injected with B16F10 (Supplemental Figure 4C). To confirm that the antitumor activity of ketorolac may be mediated by CD8+ T cell activation, we performed adoptive transfer of immune cells from preoperative ketorolac-treated long-term survivors after LLC resection into naive mice. Splenocyte or CD8+ T cell transfer from long-term ketorolac-treated survivors inhibited LLC growth compared with that of control mice that received splenocytes or CD8+ T cells from naive mice (Figure 6, E and F, and Supplemental Figure 5, A–D).

Single-cell profiling of immune cell populations in response to ketorolac. To characterize the ketorolac-mediated immunomodulatory response, we utilized droplet-based single-cell RNA-Seq (scRNA-Seq) to obtain single-cell resolution transcriptomes of splenic tissues from control and ketorolac-treated mice on day 7 after LLC resection. The transcriptome profiles of 1864 and 2429 individual cells from spleens of 2 control and 2 ketorolac-treated mice, respectively, revealed that ketorolac modulated the immune landscape by altering the relative abundance and transcriptome profiles of T cells and granulocytes. Standard cluster analysis of cells based on their most variably expressed genes in the scRNA-Seq transcriptomes is shown in the projection of gene expression space onto a single 2D space using t-distributed stochastic neighbor embedding (tSNE) (Figure 7A). The 2D plot contains cells
from both ketorolac-treated and control samples analyzed as 1 concatenated data set. Analysis of marker genes assigned the 17 identified robust clusters to T cells, B cells, erythroid cells, NK cells, granulocytes, neutrophils, macrophages, and dendritic cells (Figure 7A). Only 1 cell cluster was mouse specific and unrelated to treatment, while the majority of clusters were formed by all mice and represent known cell types — indicating minimal batch or mouse effect (Figure 7A). Ketorolac-treated spleens differed from control in relative cell-type abundance and gene expression states of individual cells.

At the level of cell-type abundance, with the exception of a few clusters that contained only or predominantly cells from control samples, the clusters contained varying proportions from both control and ketorolac-treated mice (Figure 7B). In both mice, ketorolac increased the fraction of splenic CD3d+ T cells compared with those of control, from 9.12% to 19.1% (clusters 1 and 13 in Figure 7A). One T cell cluster (cluster 13 in Figure 7A) was enriched in exhausted T cells (as determined by expression of markers PD1, CTLA4, and TIM3) from 1 control mouse, while both ketorolac-treated mice had low numbers of exhausted T cells (Figure 7, B and C). Moreover, the proportion of memory T cells (IL7r+) (cluster 1 in Figure 7A) increased from 32% in the 2 control spleens to 52% in the 2 ketorolac-treated spleens (Figure 7C). Although T cell–subtype abundance varies considerably between individuals (67), this finding is consistent with systemic activation of T cell immunity in the ketorolac-treated mice. This constellation suggests that ketorolac may improve T cell antitumor immunity and the presence of exhausted PD1+ T cells is consistent with ketorolac’s synergism with an anti-PD1 inhibitor (Figure 6, A and B).

At the transcriptome level within the T cell clusters, shifts in cell phenotypic states of control and ketorolac-treated mice (enrichment of cells from 1 mouse in a subregion of a cluster, Figure 7A) are apparent in the tSNE plots. Utilizing a systematic quantitative analysis, we focused on T cells and identified genes that were significantly enriched in each cluster (P < 0.01) and then performed a pathway analysis on these genes for the control and ketorolac-treated mice independently. Such gene ontology analysis suggested that distinct upstream regulators are significantly activated or inhibited in the different T cell clusters from control and ketorolac-treated mice (Figure 7D). The upstream regulator analysis (68) on genes associated with the exhausted T cell cluster in the control spleens indicated states controlled by transcription factor GATA3 and the cytokine VEGFA, which are associated with angiogenesis and Th2 polarization (69). In contrast, the same analysis in spleen cells from ketorolac-treated mice suggested activation of a state under control of the transcription factor 7 (TCF7) and the cytokines TNF-α, IFN-γ, and IFN-α (Figure 7D), which are associated with activated cytotoxic T cells. Of note, TCF7, which is associated with memory T cells and implicated in rescuing T cells from exhaustion by anti-PD-1 therapy (70), was activated in the CD8+ T cells of ketorolac-treated mice.

In addition, scRNA-Seq analysis demonstrated reduced Ly6g+ granulocytes in spleens of both ketorolac-treated mice (35 out of 2429 cells, 1.4%) as compared with the control mice (65 out of 1864 cells, 3.5%) (Figure 8A, cluster 12 in Figure 7A). A significant global shift in gene expression profiles of granulocytes from ketorolac-treated versus control mice was not observed. However, the proportion of Mmp9-expressing Ly6g+ cells was significantly higher in the spleens of control compared with ketorolac-treated mice (Figure 8A). MMP9 is a critical protein that promotes the expansion of Ly6g+ myeloid-derived suppressor cells (71). Moreover, upstream regulator analysis (68) of the granulocyte cluster indicated that NF-κB and PI3K were significantly activated in granulocytes from control mice compared with ketorolac-treated mice (Figure 8B), which is consistent with the suppressive activity of NSAIDs (72). The pathways and functions enrichment analysis also depicted alterations in triacylglycerol, carbohydrate, and lipid metabolism in ketorolac-treated granulocytes (Supplemental Table 1). We speculate that the low PI3K activity in the ketorolac-treated samples may decrease glycolysis (73), the major pathway of energy generation for granulocytes (74), and diminish migration (75).

Discussion

Here, we demonstrate that preoperative, but not postoperative, ketorolac and/or resolvins eradicate micrometastases in multiple tumor-resection models. While we cannot exclude minimal residual disease due to individual disseminated malignant cells, the elimination of metastatic recurrence by preoperative ketorolac resulted in long-term survival after tumor resection. These interventions also prevented dormancy escape induced by surgery or chemotherapy in several tumor types. The antitumor activity of ketorolac is dependent on a T cell–mediated response, as its activity was enhanced by immune checkpoint blockade and abrogated in athymic mice. Consistent with the immunohistochemistry, single-cell transcriptomics demonstrated increased CD4+ and CD8+ T cells in the spleens of ketorolac-treated mice as well as a shift in the proportions of T cell subtypes, indicating an increase in memory T cells and reduction of exhausted T cells. The T cell response may be specific for tumor cells, since ketorolac-treated mice were protected against a secondary challenge with the same tumor type, but not from an unrelated type. Moreover, adoptive transfer confirmed that the protective antitumor activity of ketorolac was T cell mediated, as no tumor growth was observed in mice that received T cells from ketorolac-treated long-term survivors. Therefore, targeting cancer therapy–induced inflammation with preoperative ketorolac and/or resolvins may reduce tumor recurrence and metastatic outgrowth via a T cell response.

Our study provides insight into the multifaceted roles of cyclooxygenase enzymes and their products in tumor biology. Specifically, we establish the importance of inhibiting COX-1 while maintaining COX-2 activity to control tumor recurrence or metastasis. These results shed light on the conceptual framework of inflammation and adaptive immunity in cancer. For instance, COX inhibition is generally thought to contribute to the prevention and control of tumor growth (38, 76). In the context of surgery, the NSAID meloxicam was recently reported to suppress dormancy escape of micrometastatic lesions in mouse models (2). However, we show that COX-2 inhibition may hinder the antitumor activity of ketorolac via impairment of the resolution of inflammation. In fact, selective COX-2 inhibitors have not improved recurrence-free survival in the clinic (77–81). Rather, chronic COX-2 inhibition or NSAIDs (e.g., sulindac) are linked to increased risk of breast and hematological cancers and can result in resistant adrenomas and breakthrough carcinomas (82, 83).
Moreover, while a combination of COX-2 inhibitors with adjuvant temozolomide following resection of glioblastoma extended progression-free survival, the COX-2 inhibitors also increased the rate of metastasis (84).

In addition, COX-2-derived PGE₂ exhibits complex and opposing activities. PGE₂ has been implicated in the suppression of antitumor immunity (85–87), as it can hinder antigen presentation, inhibit T cell and NK cell effector functions, and promote the activity of regulatory T cells (36, 85, 88). In contrast, PGE₂ may be necessary for optimal CD8⁺ T cell response (38, 89), supporting our finding that baseline COX-2 is critical for the antitumor immune response of ketorolac. PGE₂ also plays a critical role in the termination of inflammation, as it is required for a bioactive lipid-class switching to generate SPMs that promote the resolution of inflammation (40). The proresolution activities of PGE₂ on both the innate and adaptive immune system (12) may explain why selective COX-2 inhibition with celecoxib impaired the antitumor activity of preoperative ketorolac (Figure 2C).

The importance of COX-1 inhibition in cancer is poorly characterized and has not been translated to cancer patients (38). TXA₂ synthesis is independent of COX-2 (90), which is consistent with our finding that the antitumor activity of preoperative ketorolac is mediated by COX-1/TXA₂ inhibition. In addition, 20% of mice treated preoperatively with the antiplatelet agent clopidogrel demonstrated long-term survival in our tumor-resection model, consistent with reports showing that clopidogrel prevents carcinogenesis by restoring antitumor immunity, including increasing the number of tissue CD8⁺ T cells (91). Clopidogrel also stimulates CD4⁺ and CD25⁺ T cells in an atherosclerosis model (92). Studies suggest a direct role for TXA₂ in dendritic cell maturation and neutrophil migration (90), which may account for our genetic and pharmacologic data on the role of the TXA₂ receptor in reducing postresection tumor recurrence.

Our findings have important therapeutic implications. First, ketorolac may increase long-term survival in multiple cancer types if administered preoperatively, rather than postoperatively, per current standards of care. Second, while ketorolac is a simple, inexpensive, and relatively nontoxic treatment, potential concerns include the risk of bleeding, wound dehiscence, and acute kidney injury. These side effects were not noted in a human retrospective study (34). In contrast, SPMs dampen inflammatory mediator release from platelets and do not appear to increase the risk of bleeding nor to enhance the hemostatic function of platelets (12, 93). In our animal studies, ketorolac and resolvins demonstrated synergistic antitumor activity without overt toxicity. Third, our results suggest that coadministration of preoperative ketorolac and immune checkpoint inhibitors may provide optimal therapeutic efficacy, consistent with recent studies (2, 24, 25). High-risk stage III melanoma may be an ideal setting to assess the potential therapeutic benefit of combining ketorolac and checkpoint inhibitors, as checkpoint inhibitors alone have been shown to decrease risk of recurrence (94). Fourth, although adjuvant chemotherapy increases overall survival in select cancer patients, it may also harbor inherent tumor-promoting activity (9, 10, 18, 95–97) limiting its overall efficacy, including inflammation-associated impairment of antitumor immunity that could stimulate micrometastatic disease. Indeed, administration of chemotherapy within 7 days of surgery was detrimental to achieving effective antitumor T cell immunity, which may be due to cytotoxicity on proliferating T cells. Even when administered several weeks after resection, chemotherapy appears to abrogate T cell memory and may increase the likelihood of recurrence. Fifth, dormant tumor cells are typically resistant to adjuvant chemotherapy (98), and chemotherapy can awaken dormant micrometastases. Although we did not specifically study the combination of resolvins and ketorolac with chemotherapy, tumor-dormancy escape was inhibited in a subset of mice when ketorolac was administered alongside chemotherapy (Figure 1, F–H). We also found via LC-MS/MS-based profiling that ketorolac stimulated an increase in plasma LXA₃. Moreover, systemic treatment with resolvins inhibits chemotherapy-stimulated tumor growth in multiple tumor models (9). Collectively, our data suggest that flanking chemotherapy with antiinflammatory or proresolution therapies may be a novel approach for cancer treatment. Sixth, cancer patients in remission may benefit from preoperative ketorolac or resolvins prior to surgery, since surgery or even biopsy can induce tumor-dormancy escape or metastasis (1, 6, 8). The relapse pattern following delayed reconstructive surgery in breast cancer patients is bimodal, suggesting a systemic action on dormant micrometastases from surgery (30). Seventh, although it may be tempting to enroll patients at highest risk for recurrence in trials of ketorolac or resolvins, these patients are likely to receive neoadjuvant or adjuvant chemotherapy, radiation (encompassing draining lymph nodes), and/or have their draining lymph nodes resected per current clinical guidelines. These interventions may counteract the induction of an effective T cell immune response. It may therefore be prudent to first conduct small biomarker endpoint studies to assess the impact of preoperative ketorolac and/or resolvins on T cell response via monitoring activation of CD8⁺ cells after surgery, T cell response to predicted neoantigens, T cell receptor diversity, or single-cell sequencing. Thus, if neoadjuvant chemotherapy negates an antitumor T cell response despite administration of preoperative ketorolac, such patients would then be excluded from a randomized prospective study.

Collectively, our data suggest a paradigm shift in clinical approaches to resectable cancers. Over the last century, the field has evolved from a “more is better” Halstedian stance with increasingly radical surgeries to a view of early stage cancer as a systemic disease, resulting in the adoption of adjuvant and neoadjuvant chemotherapy. Now, we and others (2) are showing that it may be possible to eradicate micrometastatic disease and dormant tumor cells without chemotherapy. Here, we demonstrate that unleashing T cell immunity by preoperative suppression of systemic inflammation or stimulation of inflammation resolution exhibits potent antitumor activity, even curing mice of micrometastases. Pharmacological enhancement of resolution via exogenous resolvins (demonstrated here with RvD2, RvD3, and RvD4) at ng/d doses or omega-3 fatty acid supplementation restores endogenous SPMs. Moreover, ketorolac and resolvins demonstrate synergistic antitumor activity. Thus, simultaneously blocking proinflammatory responses with ketorolac and activating endogenous resolution programs via resolvins may represent a novel approach for preventing systemic recurrence in the context of locoregional disease.
Methods

Tumor resection. Tumors were resected at 1500–2000 mm³. 10⁴ LLC cells (ATCC) were subcutaneously injected into male C57BL/6J, SCID, athymic C57BL/6J, TP KO, WT, or COX-2-KO mice (Jackson Laboratory). Experiments were repeated 3 times with similar results. For orthotopic tumors, 5 × 10⁴ 4T1 (ATCC) or E0771 (CH3 BioSystems) were injected into the fourth mammary fat pad of female BALB/cj or C57BL/6j mice, respectively.

Drug administration. Drugs were administered preoperatively (2 hours before surgery), at the time of surgery, or postoperatively (2 hours after surgery). For chemotherapy, mice were treated with preoperative ketorolac (7.5 mg/kg) and a postoperative dose of cispalatin (5 mg/kg) on day 7 after tumor resection. For immune-checkpoint blockade, mice were treated preoperatively with anti-mouse PD-1 (CD279; clone RMP1-14) (200 μg/mouse; Bio X Cell). For COX inhibition, mice were treated preoperatively with FR122047 (20 mg/kg), or aspirin (10 or 30 mg/kg). For TXA2 inhibition, mice were treated preoperatively with indomethacin (3 mg/kg), ibuprofen (30 mg/kg), diclofenac (10 mg/kg), TFAP (30 mg/kg), SC-560 (30 mg/kg), celecoxib (60 mg/kg), and clopidogrel (0.5 mg/kg). For T cell depletion, anti-mouse CD4 (clone GK1.5), anti-mouse CD8 (clone 53-6.72), or isotype control (rat IgG2b) obtained from Bio X Cell was utilized (200 μg/mouse q3 days). For PGE2 studies, mice were treated preoperatively with ketorolac and a PGE2-neutralizing antibody (Cayman Chemical) (200 μg/mouse q3 days) or isotype control (rat IgG2b). Resolvins (RvD2, RvD3, or RvD4) (15 ng/μl/mouse) were administered via miniosmotic pump (Alzet Inc.) 2 hours prior to tumor resection or laparotomy. Meloxicam SR was administered after surgery per IACUC-approved protocol.

Laparotomy. C57BL/6j or RAG1-KO male mice (Jackson Laboratory) were injected with 10⁴ LLC, 10⁴ B16F10, or 10⁴ EL4 cells and subjected to laparotomy under isoflurane inhalation anesthesia. Bowels were removed, placed on a sterile sheet for 4 minutes, and returned to the peritoneum. The skin was sutured with 4-0 chromic gut absorbable sutures. Tumor size was measured by caliper (width² × length × 0.52 = mm³).

Chemotherapy-stimulated cancer. For dormancy models, 10⁴ LLC, EL4, or CT26 cells (ATCC) were subcutaneously injected into male C57BL/6j (LLC and EL4) or BALB/cj (CT26) mice. Cispalatin (5 mg/kg q5 days), vincristine (1 mg/kg q7 days), or 5-FU treatment (30 mg/kg q3 days) was initiated on the day of tumor cell injection. For combination therapies, ketorolac (7.5 mg/kg) was administered the day before, day 0, and day after cisplatin or vincristine as well as the day before and day of 5-FU treatment.

Tumor rechallenge. Preoperative ketorolac- or RvD2-treated mice that survived 90 days after LLC resection and naive age-matched mice were challenged with 10⁴ LLC via subcutaneous injection. On day 90 after LLC rechallenge, the LLC tumor-resected mice treated with preoperative ketorolac or RvD2, which did not grow tumors, were subcutaneously injected with 10⁴ B16F10.

Preoperative ketorolac-treated LLC tumor-bearing mice (10⁴ cells) were subjected to a laparotomy. Ninety days after laparotomy, these mice and naive age-matched mice were challenged with 10⁴ LLC via subcutaneous injection. On day 90 after LLC rechallenge, the preoperative ketorolac-treated mice subjected to laparotomy, which did not grow tumors, were subcutaneously injected with 10⁴ B16F10.

Adoptive transfer. Splenocytes were obtained as follows: spleens from preoperative ketorolac-treated mice after LLC resection oragematched naive C57BL/6j mice were dissociated and filtered through 40 μm strainers. CD8α+ T cells were isolated from this population by magnetic selection using a mouse CD8α+ T Cell Isolation Kit (Miltenyi Biotec). Splenocytes or isolated CD8α+ T cells were stained with CD8α APC-conjugated antibody (clone 53-6.7; R&D systems) and CD3 FITC-conjugated antibody (clone 17A2; BioLegend). Staining was assessed via BD LSR Fortessa (BD Biosciences) at the DFCI Cytometry Core and analyzed using FlowJo software (Tree Star Inc.). Splenocytes (6 × 10⁶ cells/mouse) or isolated CD8α+ T cells (3 × 10⁶ cells/mouse) were intravenously injected into C57BL/6j mice.

Immunohistochemistry. Slides were incubated with FOXP3+, CD4+, or CD8+ (Abcam; 1:100) at 4°C overnight. TSA Biotin (PerkinElmer) was used for signal amplification. The Zeiss A1 Scope, Axiocam Icc5, and Zeiss efficient navigation software (Zeiss) were used for imaging slides (10–20 fields/tumor). Immune cells per field were quantified via ImageJ.

LC-MS/MS. Plasma from preoperative ketorolac-treated and control mice after LLC resection was analyzed as described (99), with a Shimadzu LC-20AD HPLC and a Shimadzu SIL-20AC autoinjector (Shimadzu Corp.) paired with a QTrap 6500 (ABSciex).

scRNA-Seq analysis. Spleens from control and preoperative ketorolac-treated mice at 7 days after LLC resection were processed using the 10x genomics approach. Single-cell libraries were prepared using the Chromium 3 reagent kit v2 and sequenced using NextSeq 500 platform to generate approximately 50,000 reads/cell. scRNA-Seq data after standard quality control was aligned to the reference genome (mm10) using the 10x Cell Ranger pipeline. Preprocessed and filtered normalized data were subjected to unsupervised analysis using PCA (Seurat v2.0 Bioconductor package; ref. 100) to identify principal components with significant variation that was used as input for tSNE analysis (101) to determine overall relationship among cells. Cells with similar transcriptome profiles were clustered together, and the clusters were subsequently annotated to different cell types based on expression of specific transcripts, e.g., T cells (Cd3d+), B cells (Cd19+, Cd79a+, Cd79b+, etc.). Transcripts significantly associated with a particular cell type were identified by comparing the expression profile of the target cell with the rest of the cells using nonparametric Wilcox’s test (P < 0.01) and fold change (>1.2).

Identification of treatment-altered genes and pathways in specific cell types. To determine the effect of treatment on specific cell types, comparative analysis of cell abundance was performed on the control and ketorolac-treated samples. Comparative analysis of the transcriptome profiles of each cell type between ketorolac-treated and control groups was performed using a linear model for microarray analysis approach in R language (102). Pathways/Functions enrichment and systems biology analyses using the Ingenuity Pathway Analysis software package (IPA 9.0; QIAGEN) were performed on transcripts that were significantly associated with different T cell and granulocyte clusters or differentially expressed in the same cell types between treatment and control groups.

Statistic. For in vivo experiments, Student’s t test and ANOVA were utilized. Student’s t test was utilized to evaluate significance of in vitro experiments. The Kolmogorov-Smirnov test was used to evaluate the assumption of normality of continuous variables, and no significant departures from normality were detected. Summary data are reported as mean ± SEM. Longitudinal tumor growth data were analyzed using 2-factor repeated-measures mixed effects ANOVA with
the Greenhouse-Geisser F-test to assess overall group differences followed by Tukey’s post hoc comparisons, where treatment was considered the between-subjects factor and serial tumor measurements the within-subjects factor. One-way ANOVA was used to compare the groups with respect to cytokines and biomarker variables. Survival after tumor resection was analyzed using the Kaplan-Meier product-limit model with the log-rank test to evaluate survival differences over time between treatment groups. P values of less than 0.05 were considered statistically significant.

Study approval. Animal studies were approved by the Institutional Animal Care and Use Committee at Beth Israel Deaconess Medical Center.

Author contributions
DP, MWK, SH, MB, VS, CNS, and VPS designed research. DP, JY, AG, MMG, MLS, SSB, DRB, JC, BAS, JP, HY, AF, SJS, DSF, and MB performed research. MAS and BDH contributed reagents and analytic tools. DP, SJS, MB, CNS, and VPS analyzed data. DP, MB, AG, MMG, MWK, SH, and VPS wrote the paper.

Acknowledgments
We gratefully acknowledge Steve Moskowitz (Advanced Medical Graphics) for photography and preparation of the figures and thank Kristen Lehner, Donna Vatnick, and Chantal Barksdale for excellent technical assistance. This work was supported by National Cancer Institute grants RO1 OCA170549 (to DP and CNS), ROCA148633 (to DP), and RO1GM038765 (to CNS); Beth Israel Deaconess Medical Center seed funds and a gift from the Sheth family (to VPS); the Credit Unions Kids at Heart Team (to DP); the Stop and Shop Pediatric Brain Tumor Fund (to MWK); the C.J. Buckley Pediatric Brain Tumor Fund (to MWK); Alex’s Lemonade Stand (to MWK); Molly’s Magic Wand for Pediatric Brain Tumors (to MWK); the Markoff Foundation Art-In-Giving Foundation (to MWK); the Kamen Foundation (to MWK); Jared Branfman Sunflowers for Life (to MWK); the Joe Andruzzi Foundation (to MWK); National Institute of Environmental Health Science Superfund Research Program grant P42 ES004699, and National Institute of Environmental Health Science grant RO1 ES002710 (to BDH).
